

Industrial Policy and Capital Misallocation in Exporting*

Adrien Matray[†] Karsten Müller[‡] Chenzi Xu[§] Poorya Kabir[¶]

June 2026

Abstract

Trade financing through Export Credit Agencies is a key tool of modern industrial policy. We study its causal impact on trade, firm investment, and capital misallocation by using the effective shutdown of the US export credit agency, the Export-Import Bank (EXIM), from 2015–2019 as a natural experiment. First, we document that EXIM has large causal effects: comparing industries exposed and un-exposed to the shutdown, we find that exposed industries experience a product-level export reduction of approximately \$4.50 for each \$1 lost in EXIM financing. EXIM-dependent firms also experience substantial contractions in revenues, investment, and employment. Second, shutting down EXIM increases capital misallocation because firms with high marginal revenue product of capital (MRPK) disproportionately contract while low-MRPK firms are largely unaffected. Terms-of-trade adjustments and freeing capital for domestic producers do not appear to offset these losses empirically. Our results indicate that even in advanced economies with developed financial markets, industrial policy that lowers financing constraints can raise output and improve capital allocation.

The paper has been certified as “Perfectly Reproducible” by CASCaD.

1 Introduction

A central challenge in industrial policy is identifying market failures that are both quantitatively important and empirically targetable. Much of the traditional case rests on external economies of scale, whose magnitude and location are often difficult to measure. In this paper, we study a complementary rationale for intervention, which is that financing constraints in the private market lower output and generate capital misallocation.

Export Credit Agencies (henceforth “ECAs”) are among the most prominent tools of industrial policy, and they are built on this rationale: by financing firms’ exporting activity, they can ease constraints in the private market and stimulate the domestic economy. ECAs are ubiquitous, operating in over one hundred countries that together generate more than 92% of global trade (Matray, Mueller, Xu and Shen, 2026), they are especially prevalent among advanced economies with well-developed financial markets (Juhász, Lane, Oehlsen and Pérez, 2022). Yet despite their prominence, the causal effects of these institutions on a country’s exports, firm behavior, and capital allocation remain poorly understood.

The role of financing-based industrial policy in shaping the real economy has been the subject of a heated debate. The economic rationale in favor of intervention by ECAs is that exporting is a strategic activity that provides growth opportunities for productive firms, but that market imperfections in financing cross-border transactions constrain these firms to remain below their optimal size. However, ECAs are also the potential poster child for “bad industrial policy.” As government institutions, they face well-known political-economy risks, including capture by connected firms and lobbying pressures. A more critical view thus holds that ECAs primarily provide inframarginal financing to firms that would have secured funding from the private sector anyway, resulting in a pure “profit windfall” for the beneficiaries. An additional concern, even setting aside inframarginal investment from political capture, is that lowering recipients’ cost of capital may direct resources toward firms with lower marginal returns rather than those facing the tightest financing constraints, thereby distorting the allocation of capital and ultimately lowering aggregate productivity.

In this paper, we address the debate on the role of trade financing as a tool of industrial policy using a unique natural experiment: the temporary shutdown of the Export-Import Bank of the United States (EXIM) between 2015 and 2019. EXIM provides a particularly clear illustration of the economic rationale for ECAs as its official mandate states that it seeks to promote jobs and investment in the US “by facilitating the export of US goods and services [...] *when private sector lenders are unable or unwilling to provide financing*” (emphasis added).

We guide our empirical analysis with a model of heterogeneous exporters that must finance upfront working capital needs but face a borrowing (collateral) constraint, which results in capital

misallocation and lowers aggregate exports relative to a frictionless benchmark. ECA expansion takes the form of raising a common export-pledgeability parameter, which causes high marginal revenue product of capital (henceforth “MRPK”) firms to endogenously respond more than low-MRPK firms. We show that as long as the policy is identical across firms and independent of firm characteristics, or at least not so tilted towards low-MRPK firms that it undoes the within-high-MRPK firm expansion, the policy leads constrained exporters to grow and lowers capital misallocation.

The model allows us to specify a clear criterion for evaluating the success (or lack thereof) of ECA financing. We show that the policy has positive aggregate effects if the two gains (increased revenues from exports and better allocation of capital) are larger than the fiscal cost of the policy and two countervailing general-equilibrium forces, the deterioration of the terms-of-trade and a potential crowding-out of capital for domestic production.

In our empirical analysis, we draw on a comprehensive administrative dataset that records all of EXIM’s financing tools (e.g., direct loans, loan guarantees, and insurance of foreign receivables), which allows us to precisely measure firm- and product-level exposure to EXIM support. During the shutdown, the total value of EXIM’s support for exporting activities across all its programs collapsed by 84% relative to prior years. Because firms and industries differ in their reliance on EXIM, we can compare the evolution of their outcomes before and after the shutdown to identify the average and allocational impact of this large and exogenous shock to ECA-backed trade financing.

In the first part of the paper, we assess whether EXIM achieves its primary policy objective of increasing US exports. Aggregate product-level bilateral customs data allow us to estimate the effect net of market share reallocation among US exporters. Comparing exposed to non-exposed industries we find large causal effects: a \$1 reduction in EXIM support reduces US export sales in a product by approximately \$4.50, a magnitude consistent with the financing-intensive nature of cross-border trade. At the firm-level, we find that EXIM-dependent firms experience a 12% decline in total revenues, a 14% contraction in capital investment, and a 10% reduction in employment relative to non-dependent exporters.

The average effects for firms are not driven by the largest recipients of EXIM support nor those with strong ties to the government: the results are unchanged if we exclude all of the top recipients of EXIM financing, control for firms’ lobbying, exclude industries that rely on government contracts, or exclude individual industries one-by-one.

Impacted firms are unable to offset export losses through domestic sales. Given the magnitude of the shutdown’s impact on exports and firm sales, we calculate a positive pass-through from export losses to domestic sales of 3–7%. This positive pass-through is consistent with models of within-firm scope and scale (e.g., [Ding, 2024](#)), which would arise from financing frictions and internal capital

markets (e.g., [Stein, 1997](#); [Lamont, 1997](#)).

Second, we find that EXIM’s shutdown increases capital misallocation. Following the methodology of [Bau and Matray \(2023\)](#), which links changes in misallocation to within-firm changes in investment across firms with ex-ante high and low MRPK, we find that EXIM financing particularly affects investment by high MRPK firms. In contrast, low MRPK firms exhibit minimal or no changes in investment behavior. This pattern indicates that EXIM support reduces rather than increases misallocation by allowing more constrained firms to endogenously grow faster. Our effects are robust to measuring MRPK using a variety of methods, including those in [Hsieh and Klenow \(2009b\)](#) and [Baqaee and Farhi \(2020a\)](#), and adjusting misallocation measurement for differences across firms’ size and risk.

The heterogeneous responses of high- and low-MRPK firms also speak to two important dimensions of the ECA debate. First, the limited investment response among low-MRPK firms (which are typically less financially constrained) indicates that ECA support does not mechanically translate into higher growth, and in fact lends credence to concerns that such financing could be inframarginal when firms are not financially constrained. Second, because the effect of EXIM’s shutdown is concentrated among firms with high MRPK, our findings indicate that ECA support can help to overcome genuine barriers to the efficient allocation of capital. Consistent with this latter interpretation, we show that the largest effects are for firms and destination countries exhibiting high measures of financing constraints and contractual frictions. We also show that in EXIM’s case, the policy was uniformly applied, or if anything, positively tilted towards high-MRPK firms, such that the shutdown raised misallocation overall.

Throughout the paper, our identification strategy uses variation in exposure to EXIM across countries, products, and firms. In our aggregate analysis at the exporting country-by-product-by-destination level, we use variation within products across exporters, which allows us to control for changes in demand specific to a destination-product pair, as well as changes in supply specific to an exporting country that might correlate with EXIM exposure. Critically, we do not need to assume that exports of all products would have evolved similarly absent the shutdown, nor do we require random allocation of EXIM financing. Our identifying assumption is simply that there were no US-specific product-level shocks correlated with EXIM exposure occurring precisely when the shutdown began. We complement these results with a firm-level analysis that directly absorbs US-specific industry and product shocks and relaxes the identifying assumption required at the industry level, and we find similar EXIM multipliers.

Additional evidence supports a causal interpretation of our results. First, the shutdown was arguably not driven by economic considerations, but rather by the Tea Party’s political strategy of systematically blocking President Obama’s policies and nominations in Congress. Second, we

observe no differential pre-existing trends, and the reduction in the exports of affected products starts precisely after the shutdown in mid-2015, persisting all the way through 2019. As such, any concurrent shock would have had to occur exactly at the time of EXIM’s shutdown. Third, the distribution of our point estimates is tightly concentrated around the baseline estimates when we exclude individual industries and destinations, implying that our effects are not due to specific supply or demand shocks, including those that might reflect the 2018 “trade war” with China.

Our findings on capital misallocation use heterogeneity in firms’ investment responses across MRPK and financial constraints. We bin firms within progressively narrower cells when defining the high-vs-low MRPK comparison: within four-digit industries, within industry-by-size and industry-by-risk quartiles, and within industry-by-size-by-destination cells. Each successive binning absorbs more cross-firm heterogeneity in capital shares, risk-adjusted returns, and destination-specific trade costs, leaving within-cell dispersion that loads on the firm-level financing wedge. Because we focus on changes within firms, any confounding shock would need not only to coincide with EXIM exposure, but also to correlate differentially along these firm and destination dimensions at the exact time of the shutdown. Crucially, the specifications allow for trends across each dimension of heterogeneity such that declines in investment among financially constrained firms, or demand shocks from risky countries during the shutdown, cannot by themselves explain our results.

In the final part of the paper, we evaluate whether general equilibrium offsets erode these partial-equilibrium estimates. The model identifies three margins beyond firm-level responses that impact aggregate welfare: terms-of-trade movements, domestic capital-market crowd-out, and the fiscal cost of the program. Using reduced-form regressions that map naturally onto the model, we show that each force is likely small in our setting. Export unit values do not respond significantly to EXIM exposure, consistent with recent estimates of small US terms-of-trade elasticities.¹ Non-EXIM firms in industries and states most exposed to EXIM-backed firms show no detectable change in revenue, indicating no measurable crowding out of domestic production, consistent with a friction-relaxation interpretation in which EXIM unlocks capital and its small size overall (1.8% of US exports). EXIM itself operates profitably over our sample period, imposing no net fiscal cost. The standard general-equilibrium offsets are therefore not empirically significant in this setting, so the reduced-form estimates we report plausibly approximate the welfare-relevant aggregate magnitudes.

Our evidence naturally raises the question of why the private sector did not finance the exports that ended up receiving EXIM support, and why it did not extend such financing during EXIM’s shutdown. We argue that such funding gaps are endogenous to the market structure of private trade financing and can emerge for two reasons. First, fundamental frictions like asymmetric information and incomplete contracts, which are considerable in cross-border trade finance, would lead

¹See e.g., (Fajgelbaum, Goldberg, Kennedy and Khandelwal, 2020; Amiti, Redding and Weinstein, 2019; Cavallo, Gopinath, Neiman and Tang, 2021; Jiao, Liu, Tian and Wang, 2024).

profit-maximizing private banks to optimally constrain quantities to satisfy incentive compatibility constraints. Second, the specialized nature of international trade finance creates conditions in which banks may exercise market power and find it privately optimal to charge high markups and ration credit.² Under these conditions, credit rationing by private banks represents the privately optimal equilibrium response, suggesting that the funding gaps during EXIM’s shutdown were not just temporary distortions.

In contrast, by extending credit beyond the privately enforceable limit through public liquidity provision, guarantees, or instruments that directly ease collateral requirements, a public institution such as an ECA eases these financing constraints. Doing so does not require superior information about idiosyncratic risk, “picking winners,” or subsidies to the risk-adjusted cost of capital (e.g., [Itskhoki and Moll, 2019](#); [Holmström and Tirole, 1998](#); [Tirole, 2012](#)).

The financing-wedge channel at the heart of our analysis is distinct from the standard externality justifications for industrial policy, such as external returns to scale. Our framework nonetheless clarifies that ECAs can also target such social wedges in the economy while continuing to meet their own output objectives when those wedges correlate positively with financing frictions. In addition, because trade financing can target specific firm-product-destination market transactions, it can be applied selectively and thus potentially minimize introducing other costly distortions.

Related literature. Our work contributes to a growing literature providing new empirical evidence and theories on how industrial policy affects firms and economic development (e.g., [Juhász, 2018](#); [Itskhoki and Moll, 2019](#); [Kim, Lee and Shin, 2021](#); [Garin and Rothbaum, 2022](#); [Lane, 2023](#); [Choi and Levchenko, 2024](#)). Existing work studying the real effects of ECAs has focused on firm-level effects and often relied on correlations between exports and ECA credit (two exceptions are [Zia \(2008\)](#) and [Agarwal et al. \(2023\)](#)), including studies of Germany ([Felbermayr and Yalcin, 2013](#)), Austria ([Badinger and Url, 2013](#)), and Korea ([Hur and Yoon, 2022](#)). In contrast to these, the natural experiment of EXIM’s shutdown allows us to estimate the causal effect of export credit agency support in an economy with a well-developed capital market and lower risk of political capture.³ Our evidence indicates that exporting is a setting in which the channel of financing constraints is empirically relevant, and that export credit agencies are therefore likely to be an effective tool of industrial policy.

More broadly, a substantial literature shows theoretically how financing frictions lead to capital misallocation (e.g., [Buera, Kaboski and Shin, 2011](#); [Midrigan and Xu, 2014](#); [Moll, 2014](#); [Kehrig and](#)

²[Rysman, Townsend and Walsh \(2022\)](#) and [Cavalcanti, Kaboski, Martins and Santos \(2023\)](#) show that even in competitive banking environments, pre-emptive behavior allows banks to exert market power to maximize profits. This behavior results in capital misallocation, as banks restrict credit despite borrowers having high returns to capital.

³[Kurban \(2022\)](#) studies the aggregate effect of the US EXIM shutdown focusing on US industries, and [Benmelech and Monteiro \(2024\)](#) studies the specific case of Boeing. Our empirical results are quantitatively identical when we remove Boeing from the analysis.

Vincent, 2024), and empirically how government interventions can mitigate or amplify it (e.g., Bau and Matray, 2023; Carrillo, Donaldson, Pomeranz and Singhal, 2023). Our results highlight a role for ECAs as policy tools that lower misallocation by reducing trade-specific financing frictions.

While much of the literature on trade policy has focused on tariffs, we contribute to the broader literature examining how institutions and market structure in international trade affect firm behavior (e.g., Bernard, Redding and Schott, 2011), particularly in the presence of policy uncertainty (e.g., Ramondo, Rappoport and Ruhl, 2013; Pierce and Schott, 2016) and domestic frictions (Ramondo, Rodríguez-Clare and Saborío-Rodríguez, 2016). This includes work that specifically studies the connection between trade and misallocation (e.g., Khandelwal, Schott and Wei, 2013; Edmond, Midrigan and Xu, 2015; Finlay, 2021; Bai, Jin and Lu, 2024). Our analysis shows that public institutions that alleviate financing frictions, such as ECAs, can also have first-order effects on economic activity in the tradable sector.

Finally, we contribute to the empirical literature on finance and trade. Existing work has primarily focused on how changes in the provision of private credit affects firms’ export activity (e.g., Amiti and Weinstein, 2011; Manova, 2013; Paravisini, Rappoport, Schnabl and Wolfenzon, 2014; Demir, Michalski and Ors, 2017; Xu, 2022; Beaumont and Lenoir, 2023; Bruno and Shin, 2023), and how banking networks can affect trade patterns (Niepmann and Schmidt-Eisenlohr, 2017a,b; Xu and Yang, 2024). Models of how financing frictions and financial development can affect international trade include Caggese and Cuñat (2013), Chaney (2016), and Leibovici (2021). We extend this literature in two ways. First, we identify the effect of a shock to credit supply specific to exports separately from a broader effect of changes in financing conditions that would affect firm production in general, and thus indirectly also its exporting behavior. Second, our context focuses on the role of government-backed export credit and assesses both its impact on average firm outcomes as well as the allocation of capital.

2 Institutional Context

This section discusses the importance of financing for export sales and the role of export credit agencies. We provide an overview of EXIM and its shutdown from 2015–2019.

2.1 Financing Needs of Trade

Export transactions involve distant counterparties operating in different legal jurisdictions, which creates two distinct financial challenges for exporters. First, firms must finance extended working capital needs arising from the significantly longer delay between the time they pay for their inputs and the time they receive payment from their buyers relative to domestic transactions. Second,

exporters face heightened counterparty risk across different legal jurisdictions.⁴

Financial institutions play a critical role by providing not only capital but also risk mitigation through specialized financial instruments such as export credit insurance, factoring, and receivables financing, which effectively transform invoiced exports into secured financial instruments and protect against international trade risks.

Frictional markets. With access to complete and frictionless financial markets, exporters can finance and insure all profitable opportunities and invest optimally based on their productivity. By contrast, financially constrained exporters must operate at suboptimal scale because they cannot fully cover working capital requirements or adequately insure against international cash-flow risks (Rampini and Viswanathan, 2010).

Three frictions are particularly relevant for financing and insuring international trade. First, **firm-specific frictions** stem from asymmetric information between lenders and borrowers (e.g., Stiglitz and Weiss, 1981) and incomplete contracts that restrict firms' ability to credibly pledge future cash flows (e.g., Banerjee and Newman, 1993). These informational and contractual limitations lead banks to ration credit as a profit-maximizing strategy to maintain incentive compatibility. This rationing creates significant financing constraints, particularly affecting firms with limited collateral or credit history.

Second, **destination-specific frictions** characterize cross-border transactions due to exacerbated information asymmetries and contractual uncertainties with foreign counterparties, especially those with weak institutions or unfamiliar legal frameworks. Financial institutions respond by imposing stricter credit limits for exports to these destinations, generating additional financing constraints that impede otherwise economically viable international transactions.

Third, **market power** in international finance enables profit-maximizing financial institutions to impose markups that artificially constrain credit and insurance. This market power derives from the substantial fixed costs of establishing international operations, including developing correspondent banking networks, acquiring market-specific expertise, and implementing complex cross-border compliance systems.⁵

Any one of these three frictions (contractual limitations, informational barriers, and bank market power) would generate systematic underprovision of export financing, forcing exporters to artificially constrain investment below the optimal level dictated by their productivity (Manova, 2013).

⁴Counterparty risk is inherent regardless of payment terms: buyers risk non-delivery after prepayment; sellers risk non-payment after shipping. Schmidt-Eisenlohr (2013) and Antras and Foley (2015b) provide theoretical frameworks for these contractual frictions and their implications for trade financing.

⁵Market power in international finance typically exceeds that in domestic lending markets due to the specialized investments required. Banks need established correspondent relationships or foreign subsidiaries, detailed knowledge of counterparties' credit and legal environments, and compliance systems for international regulations that impose additional due diligence. These high, heterogeneous fixed costs naturally create concentrated markets dominated by a few large institutions (e.g., Niepmann and Schmidt-Eisenlohr, 2017a; Paravisini, Rappoport and Schnabl, 2023).

This financing gap also likely results in misallocating capital among exporting firms, skewing the distribution of capital toward financially unconstrained firms with lower MRPK (Chaney, 2016).

2.2 Export Credit Agencies (ECAs)

ECAs are mandated to support domestic exporters and overseas investments by providing financial services that commercial lenders are unwilling or unable to offer due to commercial, political, or country risks. We refer interested readers to Matray, Mueller, Xu and Shen (2026) on ECAs broadly around the world and Appendix C.4 for more details on EXIM in particular.

Role and tools of ECAs. ECAs relax the constraints on financing exports through two primary types of products: loans and insurance.

- Loans predominantly take two forms: *direct loans* and *loan guarantees*. In the former, ECAs lend directly; in the latter, ECAs guarantee payment on principal and interest in case of default, thereby expanding the amount commercial banks are willing to lend per dollar of the firm’s pledgeable net worth.
- Insurance protects exporters against non-payment by foreign buyers due to commercial risks (buyer default, insolvency, payment delays) and political risks. By doing so, it transforms uncertain export receivables into secure assets that can be used as collateral, raising the pledgeable value of an export sale.

Economic incidence of ECA funding. Operationally, ECAs predominantly structure programs so that disbursed funds flow directly to domestic exporters, even when the official borrower is a foreign importer such that the foreign firms cannot redirect the funds. This design underscores the core objective to target domestic export activity constrained by private-sector financing gaps.

Regardless of whether financing is formally extended to the exporter or importer, ECA funding serves the same economic function: easing financial constraints that impede international trade. When exporters receive direct financing, their constraints are relaxed, enabling them to fulfill orders they otherwise would be unable to produce or deliver. When importers receive financing, they can directly pre-pay exporters to enable production.

2.2.1 EXIM’s Implementation Framework and Institutional Design

Established during the New Deal, EXIM is the US’s official ECA, and its mandate is to support US jobs by supplying export financing.⁶ We highlight the main elements of EXIM that are important for our analysis (see Appendix C.4 for details of each point below).

⁶EXIM’s initial mission in 1934 was to support both exports and imports. The bank subsequently focused on exports, although the name remained unchanged.

EXIM offers all the standard ECA instruments: direct loans, loan guarantees, working-capital guarantees, and credit insurance (Appendix C.4.2). For clarity, in the rest of the paper, we use the term “**EXIM financing**” to encompass **all** instruments used by EXIM.

Market role and positioning. EXIM operates as a residual financier of export-credit constrained firms by design: firms must demonstrate they could not secure financing from private lenders. This design precludes cream-skimming and makes EXIM complementary to the private market.

Institutional advantages. As a US government agency, EXIM also has access to information-sharing arrangements (with the State and Treasury Departments, US embassies, and the Trade Promotion Coordinating Committee) and enforcement technologies (e.g., conversion of commercial claims into sovereign obligations) that the private sector does not (Appendix C.4.3). These institutional advantages are not necessary for the welfare argument developed in our model, but they help to explain why EXIM operates in markets where private financiers do not.

Operational constraints. EXIM operates under three key constraints: annual Congressional appropriations that strictly constrain EXIM’s balance sheet size and prevent the institution from reinvesting its profits to grow, a statutory requirement to operate at zero or negative net subsidy under the Federal Credit Reform Act, and a 2% cap on its default rate.

Takeaway. EXIM is designed to fund profitable but liquidity-constrained export projects, particularly in markets in which exporters face informational or contractual frictions that would exacerbate private market financing frictions ⁷

2.2.2 The 2015 Shutdown of EXIM’s Operations

Two events in July 2015 led to a significant disruption in EXIM’s operations. First, on July 1st, EXIM’s charter, which requires periodic re-authorization by Congress, was allowed to lapse for the first time since the agency’s inception in 1934. Second, on July 20th, the Bank’s board of directors lost its quorum, which was necessary for many of EXIM’s activities.

The lapse in EXIM’s charter was primarily caused by a political dispute in the highly polarized environment following the 2012 Presidential and 2014 midterm elections. EXIM’s lack of board quorum, which lasted for much longer than the initial shutdown, was led by Republican Richard Shelby, the chair of the Senate Banking Committee, opposing all nominees for board positions during the second Obama Administration.⁸

During this period, the bank’s operations collapsed by 84% relative to the years prior even

⁷We would like to thank Natalia Ramondo for suggesting this summary of EXIM’s objective as financing “solvent but liquidity-constrained firms.”

⁸An article in the New York Times on February 2016 described Shelby as having the “distinction of running the only committee in the Senate that has not acted on a single nominee in this Congress.”

as applications stayed constant.⁹ Figure 1 shows the change in the agency’s total supply of new financing over all its different instruments.

Figure 1: EXIM’s Supply of Trade Financing

Notes: This figure plots the quarterly amount of new trade financing issued by EXIM in \$ billions.

3 A Model of Export Financing

This section develops a static framework of export financing that provides structure for the empirical analysis. Exporters must finance upfront working-capital needs and face a financing (collateral) constraint arising from the limited pledgeability of future export revenues. Because exporters are heterogeneous in their wealth, this constraint generates low export levels and capital misallocation. A policy that relaxes export-finance constraints raises exports and can lower capital misallocation because ex-ante more constrained exporters respond more per unit of support. This reallocation force is present even under a uniform policy that applies to all firms similarly and does not condition on firms’ productivity, and is reinforced when support is tilted toward more constrained firms. The overall growth in capital and the reduction in capital misallocation raise aggregate revenue and welfare provided they outweigh three countervailing forces: falling export prices (a terms-of-trade loss), a higher economy-wide cost of capital that may crowd out domestic production, and the fiscal cost of the program. The model shows how to map each of these forces (firm-level responses, export revenue, capital misallocation, capital-market crowd-out, and terms-of-trade offsets) into regression coefficients that we can estimate in the data. Appendix E provides the full equilibrium system, derivations, and detailed proofs.

⁹Appendix C.4 provides detailed summary statistics on the composition of EXIM’s portfolio by product, program type, and firm characteristics during the pre-shutdown period (2007–2014). When EXIM regained its full operational status, it had accumulated a pipeline of \$40 billion active applications.

3.1 Environment

Markets and revenue. Home firms i sell in two destination markets m , the domestic market d and the export market x . Following the small-economy logic in [Bartelme, Costinot, Donaldson and Rodriguez-Clare \(2024\)](#), Foreign is treated as exogenous: Foreign expenditure and Foreign firms' prices, both in Home and in the export market, are fixed from Home's perspective. ~~the Rest of the World (RoW) is treated as exogenous such that RoW expenditure and Foreign firms' prices (i.e., both the prices at which Foreign firms export to Home and the prices at which they sell in the RoW market) are fixed from the perspective of Home.~~ [YT: I found that in most of the notations, we use Foreign rather than RoW. Do you think it's good to completely replace the RoW with Foreign (denote as F)?] [CX: how is this? And given this change, can you replace as necessary in the appendix?] Consumers have CES preferences over a continuum of differentiated varieties, and each firm is a monopolistic supplier of a single variety, so firms face a downward-sloping demand curve with constant elasticity. Firms choose capital inputs (and therefore output and prices) taking the rental rate of capital r_k as given to maximize profits. With constant-returns production, this gives the reduced-form firm revenue function:

$$R_{i,m} = Z_{i,m} k_{i,m}^\alpha, \quad m \in \{d, x\}, \quad \alpha \equiv \frac{\sigma - 1}{\sigma} \in (0, 1), \quad (1)$$

where $k_{i,m}$ is capital used to serve market m , and $Z_{i,m}$ collects market size, the destination price index, and firm productivity, and σ is the elasticity of substitution between goods..¹⁰ Appendix E.2 gives the CES foundation and price-index system.

Export working capital. Exporting requires upfront working capital because export sales involve longer payment lags than domestic sales.¹¹ This working-capital need has two components: a variable component equal to a share $\phi_x \in (0, 1)$ of export revenue (for instance, the working capital tied up when the exporter ships on open-account terms and is paid only after delivery), and a recurring fixed overhead $F_x > 0$ (covering for example documentation, compliance, and inventories in transit). Exporters to a common export market x borrow at the same risk-adjusted working-capital financing cost r_x^{adj} .¹²

Firm-specific financing constraints arise from limited pledgeability of firm resources ([Banerjee and Newman, 1993](#); [Kiyotaki and Moore, 1997](#)), which caps export working-capital borrowing. We

¹⁰This concave reduced-form revenue function follows from CES demand and constant-returns production, and is isomorphic to a decreasing return to scale production function that comes from a span-of-control formulation ([Buera, Kaboski and Shin, 2015](#)).

¹¹See [Hummels and Schaur \(2013\)](#); [Feenstra, Li and Yu \(2014\)](#); [Antràs and Foley \(2015a\)](#); [Aristizábal-Ramírez, Balamero-Quintana, Bonadio, Echeverri and Posso \(2025\)](#).

¹²We adopt this notation (with the superscript *adj*) to denote the risk-adjusted rate of borrowing that includes the lender's pricing of project risk; for the comparative statics it is treated as a constant for a given export market.

summarize this limited-commitment friction with a common enforcement parameter θ_x and firm-specific pledgeable net worth a_i : one dollar of firm i 's pledgeable net worth supports θ_x dollars of export working-capital finance. The export-financing constraint for firm i is therefore

$$\phi_x R_{i,x} + F_x \leq \theta_x a_i. \quad (2)$$

A firm exports if and only if export profits net of the fixed financing cost $r_x^{adj} F_x$ are non-negative:

$$(1 - r_x^{adj} \phi_x) R_{i,x}^* - r_k k_{i,x}^* - r_x^{adj} F_x \geq 0 \quad (3)$$

where $(k_{i,x}^*, R_{i,x}^*)$ are the firm's optimal export-market choices.

3.2 The Export-Finance Wedge

Exporting firm i chooses domestic-market and export-market capital to maximize

$$\max_{k_{i,d}, k_{i,x} \geq 0} R_{i,d} - r_k k_{i,d} + (1 - r_x^{adj} \phi_x) R_{i,x} - r_k k_{i,x} - r_x^{adj} F_x \quad \text{subject to (2) and (3)}. \quad (4)$$

Let $\lambda_i \geq 0$ be the multiplier on (2). The comparative statics below focus on active exporters and hold fixed the active-exporter set, so the participation constraint (3) is slack locally. The first-order condition for export capital,

$$(1 - r_x^{adj} \phi_x) \frac{\partial R_{i,x}}{\partial k_{i,x}} - r_k - \lambda_i \phi_x \frac{\partial R_{i,x}}{\partial k_{i,x}} = 0,$$

equates the marginal revenue product, net of the contractual working-capital cost $r_x^{adj} \phi_x$ and the shadow financing cost $\lambda_i \phi_x$, to the rental rate. Collecting terms gives

$$\text{MRPK}_{i,x} \equiv \frac{\partial R_{i,x}}{\partial k_{i,x}} = \frac{r_k}{1 - \phi_x (r_x^{adj} + \lambda_i)} \equiv r_k (1 + \tau_{i,x}). \quad (5)$$

The wedge $\tau_{i,x}$ can be written explicitly as

$$\tau_{i,x} = \frac{\phi_x (r_x^{adj} + \lambda_i)}{1 - \phi_x (r_x^{adj} + \lambda_i)},$$

which is monotonically increasing in the shadow price λ_i of the firm's export-financing constraint. This is the misallocation wedge of Hsieh and Klenow (2009a), with one difference: $\tau_{i,x}$ is endogenous to the pledgeability constraint rather than exogenously imposed as a tax.

Policy Intervention. A policy that improves export-finance access is modeled as an increase in pledgeability for active exporters, $d\theta_x > 0$.¹³

Lemma 1 (Inframarginal **Benchmark Policy**). *If the export-financing constraint is slack ($\lambda_i = 0$) for every firm affected by the policy, ~~If firm i 's export-financing constraint is slack and $\lambda_i = 0$,~~ then a local change in pledgeability has no effect on export capital or export revenue:*

$$\frac{\partial k_{i,x}}{\partial \theta_x} = \frac{\partial R_{i,x}}{\partial \theta_x} = 0.$$

When the constraint is slack, export scale is pinned down by the unconstrained first-order condition rather than by the firm borrowing constraint, and policy intervention is inframarginal.

3.3 Local Comparative Statics

Assumption 1 (Constrained Benchmark). *(i) Without loss of generality, assume that there are two types of firms in the Home economy. Both Home firms are active exporters, and ordered by pledgeable net worth $a_1 < a_2$ ¹⁴; (ii) both export-financing constraints (2) bind; (iii) the active-exporter set and the binding status of each export-financing constraint remain unchanged after the local perturbation $d\theta_x > 0$; (iv) firms share a common export revenue shifter, $\mathcal{Z}_{1,x} = \mathcal{Z}_{2,x} \equiv \mathcal{Z}_x$.*

We maintain Assumption 1 throughout this subsection. Because the two exporters share a common export shifter, $a_1 < a_2$ implies $k_{1,x} < k_{2,x}$ and $\text{MRPK}_{1,x} > \text{MRPK}_{2,x}$; see Appendix E.3.

Proposition 1 (Differential Investment Response). *Let $\varepsilon_i \equiv \partial \log k_{i,x} / \partial \log \theta_{i,x}$ denote firm i 's export-capital elasticity to its own pledgeability, evaluated at the common baseline $\theta_{i,x} = \theta_x$. The high-MRPK exporter (firm 1) has the larger per-unit response:*

$$\varepsilon_1 > \varepsilon_2.$$

For constrained exporters, revenue is pinned down by the financing constraint, $R_{i,x} = (\theta_x a_i - F_x) / \phi_x$. A marginal increase in a firm's own pledgeability therefore relaxes the constraint proportionally more for the initially tighter, higher-MRPK firm, which expands strictly more ($\varepsilon_1 > \varepsilon_2$).¹⁵ This differential per-unit response is the reallocation margin in the sense of **Bau and Matray (2023)**.

¹³ECA tools directly or indirectly relax pledgeability constraints (Section 2.2). In the case of the EXIM Bank, firms are eligible for export financing only if they are already exporters.

¹⁴The two-firm case keeps the notation transparent; the propositions extend to N exporters under the standard reallocation conditions of **Hsieh and Klenow (2009a)**.

¹⁵An alternative policy instrument would subsidize the common risk-adjusted working-capital borrowing cost, r_x^{adj} . That shock operates through the common marginal financing cost in (5) and moves exporters similarly within narrow cells. Appendix E.3.2 derives this contrast.

Let $k_x = k_{1,x} + k_{2,x}$ be aggregate Home export capital, and let $s_{i,x} \equiv k_{i,x}/k_x$ and $\varpi_{i,x} \equiv R_{i,x}/\mathcal{R}_x$ denote firm i 's shares of Home export capital and export revenue. Define the allocation index as

$$\Phi_x \equiv \left(\frac{k_{1,x}}{k_x} \right)^\alpha + \left(\frac{k_{2,x}}{k_x} \right)^\alpha,$$

so that the change in allocative efficiency among exporters, the firm-TFP-fixed Solow residual in the sense of Baqaee and Farhi (2020a), is:

$$d \log \Phi_x = \alpha(\varpi_{1,x} - s_{1,x}) (d \log k_{1,x} - d \log k_{2,x}).$$

To separate firms' per-unit responses ε_i from the allocation of policy support, let $d \log \theta_{i,x}$ denote firm i 's local policy dose. We call the policy *uniform* when $d \log \theta_{1,x} = d \log \theta_{2,x}$, in which case the dose-wedge covariance $\rho \equiv \text{Cov}_i(d \log \theta_{i,x}, \lambda_i)$ equals zero. More generally, $\rho > 0$ means that support tilts toward higher-MRPK firms, while $\rho < 0$ means that support tilts away from them.

Lemma 2 (Policy Design). *Allowing the policy dose to vary across firms, write each firm's realized response as the export-capital elasticity multiplied by its dose, $d \log k_{i,x} = \varepsilon_i d \log \theta_{i,x}$, the net shift of export capital toward the high-MRPK firm is:*

$$d \log k_{1,x} - d \log k_{2,x} = \underbrace{\bar{\varepsilon} (d \log \theta_{1,x} - d \log \theta_{2,x})}_{\text{policy targeting}} + \underbrace{\overline{d \log \theta}_x (\varepsilon_1 - \varepsilon_2)}_{\text{per-unit response}}.$$

The policy targeting term is weakly positive when the policy dose is larger for the firm with the higher financing wedge, i.e. when ρ is non-negative.¹⁶ The per-unit-response term is positive by Proposition 1, so $\rho \geq 0$ is sufficient but not necessary for capital to shift toward the high-MRPK firm: the shift occurs even when $\rho < 0$, provided the targeting term does not outweigh the per-unit response.

Proposition 2 (Export Capital Reallocation). *If $\rho \geq 0$, including the case of a uniform policy, a local pledgeability improvement reduces within-export capital misallocation, equivalently raising the export allocative efficiency index:*

$$d \log \Phi_x > 0.$$

The high-MRPK exporter is smaller, with higher revenue per unit of capital, so $\varpi_{1,x} > s_{1,x}$. Lemma 2 gives $d \log k_{1,x} - d \log k_{2,x} > 0$ for $\rho \geq 0$, which implies $d \log \Phi_x > 0$.

¹⁶In the two-firm benchmark, cross-firm averages are $\bar{\varepsilon} \equiv \frac{1}{2}(\varepsilon_1 + \varepsilon_2)$ and $\overline{d \log \theta}_x \equiv \frac{1}{2}(d \log \theta_{1,x} + d \log \theta_{2,x})$; and $\rho = \frac{1}{4}(d \log \theta_{1,x} - d \log \theta_{2,x})(\lambda_1 - \lambda_2)$ with $\lambda_1 > \lambda_2$. The two-term decomposition is exact for two firms; with more than two firms it carries an additional interaction term between policy doses and per-unit responses across firms. See Appendix Lemma 3 for the exact N -exporter decomposition.

Corollary 1 (Exporter-Level Business Stealing). *A pledgeability shock generates business stealing among Home exporters: while both exporters expand in levels, $d \log R_{i,x} > 0$ for $i = 1, 2$, the high-MRPK exporter gains export-revenue share, $d\varpi_{1,x} > 0$, under a uniform policy or more generally when $\rho \geq 0$; sufficiently negative targeting reverses the direction of this share reallocation.*

The total effective export-capital change is

$$E_x \equiv \underbrace{\alpha d \log k_x}_{\text{aggregate export-capital effect}} + \underbrace{d \log \Phi_x}_{\text{within-exporter reallocation effect}},$$

which summarizes the two channels through which the shock raises aggregate export revenue: an increase in aggregate exporters' investment, and a reduction in capital misallocation among exporters.

Proposition 3 (Aggregate Export Revenue). *Let $\mathcal{R}_x = R_{1,x} + R_{2,x}$ denote aggregate Home export revenue, let $\mathcal{R}_{F,x}$ denote Foreign export revenue in the export market, and let $w_x \equiv \mathcal{R}_x / (\mathcal{R}_x + \mathcal{R}_{F,x})$ denote Home's export-market share. Then*

$$d \log \mathcal{R}_x = (1 - w_x) [\alpha d \log k_x + d \log \Phi_x] = (1 - w_x) E_x,$$

Under Proposition 2, $E_x > 0$ so:

$$d \log \mathcal{R}_x > 0.$$

Proposition 3 shows that the export-revenue effect equals the effective export-capital expansion, E_x , scaled by the terms-of-trade pass-through, $1 - w_x$. The effective-capital term combines aggregate export-capital growth, $\alpha d \log k_x$, with the allocative-efficiency gain, $d \log \Phi_x$. Under Proposition 2, both components are positive.

Corollary 2 (Terms-of-Trade Offset). *Let $P_{H,x}$ denote the CES price index of Home varieties in the export market, and define Home's terms of trade as $TOT_x \equiv P_{H,x} / \bar{p}_{F,d}$, the price of Home exports relative to the fixed price of the Foreign good that Home imports. By Proposition 3, $d \log \mathcal{R}_x = (1 - w_x) E_x$, so for a given effective export-capital expansion $E_x > 0$, the revenue gain shrinks in Home's existing export share,*

$$\frac{\partial}{\partial w_x} d \log \mathcal{R}_x = -E_x < 0,$$

because export expansion lowers the Home export-bundle price relative to the fixed import price,

$$d \log TOT_x = d \log P_{H,x} < 0.$$

Intuitively, as Home expands exports, the CES price index for Home export varieties falls, $d \log P_{H,x} < 0$. With the import price $\bar{p}_{F,d}$ fixed, this decline leads to a one-for-one deterioration in Home's terms of trade, $d \log TOT_x < 0$. The larger Home's initial export-market share w_x , the stronger this price response, so a smaller fraction of the effective export-capital expansion E_x passes through to Home export revenue.

Capital-market crowd-out. Export expansion can also negatively affect Home-market production through the integrated capital market. After imposing the CES price-index equations and the Home-expenditure fixed point, write reduced-form capital demand as $\tilde{k}_d(r_k, \theta_x)$ and $\tilde{k}_x(r_k, \theta_x)$, and let $\tilde{k}_{d,r} \equiv \partial \tilde{k}_d / \partial r_k$, $\tilde{k}_{d,\theta} \equiv \partial \tilde{k}_d / \partial \theta_x$, with $\tilde{k}_{x,r}$ and $\tilde{k}_{x,\theta}$ defined analogously.

Proposition 4 (Rental-Rate Pressure and Capital-Market Crowd-Out). *Under the stability condition $K'_s(r_k) - \tilde{k}_{d,r} - \tilde{k}_{x,r} > 0$, a pledgeability improvement raises aggregate capital demand and therefore increases the equilibrium rental rate, $dr_k/d\theta_x > 0$. This rental-rate increase crowds out Home-market capital if and only if*

$$\frac{dk_d}{d\theta_x} < 0 \quad \Longleftrightarrow \quad -\tilde{k}_{d,r} \frac{dr_k}{d\theta_x} > \tilde{k}_{d,\theta}.$$

The effect on Home-market capital is ambiguous even though the policy shock unambiguously raises the rental rate of capital. While higher capital prices reduce quantity demanded along the Home-market capital demand curve, higher export income shifts that demand curve outward. Domestic crowd-out occurs only when the rental-rate effect dominates the outward demand shift.

Welfare Accounting. Under CES preferences, the representative consumer's indirect utility equals real Home income, $W = I/P_d$, with $I = \mathcal{R}_d + \mathcal{R}_x - T$, where T is a lump-sum tax on Home residents that finances the policy; the fiscal-cost term in the welfare decomposition therefore represents the net resource cost of the export-finance program.

Define the Home-market effective-capital change by $E_d \equiv \alpha d \log k_d + d \log \Phi_d$, where Φ_d is the Home-market analog of Φ_x and $d \log \Phi_d = 0$ because firms face no firm-specific Home-market wedge. Let $\chi_m \equiv \mathcal{R}_m/I$ denote the revenue share of market m in Home income and let w_d denote the Home-producer share of Home-market expenditure. Since in equilibrium the following equalities hold $D_d = I$, $\chi_d = w_d$, the local welfare change is

$$d \log W = \underbrace{\frac{\chi_x(1-w_x)}{1-\chi_d} E_x}_{\text{export revenue}} + \underbrace{\frac{\chi_d(1-w_d)}{1-\chi_d} E_d}_{\text{Home-market revenue}} + \underbrace{\frac{w_d}{\sigma-1} E_d}_{\text{Home price index}} - \underbrace{\frac{1}{1-\chi_d} \frac{dT}{I}}_{\text{fiscal cost}} \quad (6)$$

Equation (6) collects the channels above. The export-revenue term converts effective export-capital

growth into welfare: E_x contains aggregate export-capital growth and within-export reallocation, while $(1 - w_x)$ captures the terms-of-trade offset. The next two terms are Home-market effects. If rental-rate pressure reduces Home-market capital, then E_d falls and these revenue and price-index terms attenuate the welfare gain. The final term subtracts the fiscal cost of the program, scaled by the Home-expenditure fixed-point multiplier, $1/(1 - \chi_d)$. Appendix E.4 derives equation (6); the proof of Proposition 4 establishes the crowd-out condition.

3.4 Mapping the Model to the Empirics

The model guides the empirical analysis in four steps. First, Lemma 1 gives the inframarginal benchmark: if EXIM financing relaxes only slack pledgeability constraints, changes in support should not affect export capital or export revenue. The average-effect estimates in Section 5 test this benchmark by asking whether exports and firm scale fall when EXIM support is withdrawn.

Second, Lemma 2 separates the allocative effect into two objects: firms' per-unit responses to a pledgeability shock and the incidence of policy support across firms. The per-unit response is positive for allocation when high-MRPK firms react more strongly, as in Proposition 1. The incidence of support can then reinforce or offset this force depending on whether EXIM exposure is tilted toward or away from constrained firms. Section 6 therefore examines both the differential response of high-MRPK firms to the shutdown and the distribution of EXIM exposure across firms.

Third, the same heterogeneous response helps identify the channel through which EXIM operates. A change in the common borrowing cost r_x^{adj} would move constrained and unconstrained firms similarly within narrow cells, whereas a change in pledgeability θ_x makes initially constrained, high-MRPK firms respond more (Proposition 1 and Appendix E.3.2). The high-versus-low-MRPK exercise in Section 6 therefore speaks both to capital allocation and to the mechanism by which EXIM affects firms.

Fourth, the welfare accounting highlights the aggregate offsets that could attenuate these gains: terms-of-trade effects, capital-market crowd-out, and the fiscal cost of the program. We examine these forces in Section 7.

4 Data and Empirical Strategy

4.1 Data

(1) EXIM authorization data. We use comprehensive records of EXIM loan authorizations and disbursements originating from 2007 to 2022, obtained through a FOIA request. These records include the date of authorization, the amount disbursed, the export product, and the exporting

firm. Products are reported at the NAICS-4 level, which we convert to HS-4 using the concordances provided by [Pierce and Schott \(2012\)](#).

(2) Aggregate product export data. We construct a panel of bilateral trade flows at the origin-destination-product-year level using BACI ([Gaulier and Zignago, 2010](#)). We define products at the HS-6 digit level, which contains 5,047 distinct products, exported to 220 distinct destinations. We use a time-consistent definition of products from the 2007 vintage that accounts for updates to product classifications.

(3) Firm export data. We measure exports at the firm level using data from Datamyne, a private vendor that collects and cleans maritime bills of lading. Datamyne provides detailed information on individual shipments, including product codes, destination countries, and the weight of the shipped products. We match firms in Datamyne to EXIM’s loan portfolio (see Appendices [C.1](#) and [C.2](#)).

(4) Firm data. We measure outcomes for publicly listed firms from Compustat that we match to EXIM’s authorizations (see Appendices [C.1](#), [C.2](#), and [C.3](#)). Publicly listed firms account for approximately half of the value of authorizations, and they generate approximately 80% of aggregate exports.¹⁷ We measure lobbying activity using LobbyView ([Kim, 2018](#)).

[Table 1](#) reports descriptive statistics for the matched firm level dataset covering 2010–2019. 5.2% of our firm-year observations are from firms that received EXIM financing before the shutdown. The average firm has revenues of \$3.9 billion; one quarter of those sales are generated abroad.

4.2 Empirical Strategy

4.2.1 Aggregate Exports

To assess whether EXIM generates net exports for the US, we estimate dynamic difference-in-differences regressions of the following form:

$$\Delta^{2014} Export_{p,o,d,t} = \sum_{k=2010, k \neq 2014}^{2019} \beta_k \left[EXIM_{p,o} \times \mathbb{1}(t = k) \right] + \gamma_{p,d,t} + \delta_{o,t} + \varepsilon_{p,o,d,t} \quad (7)$$

where the dependent variable $\Delta^{2014} Export_{p,o,d,t}$ is the growth rate in export values relative to 2014 (the year before the shutdown), measured at the product p , exporting country o , destination country d , and year t level. Defining our dependent variable as a growth rate eliminates all time-invariant differences at the product-origin-destination level, which is equivalent to first-differencing

¹⁷The US Census Bureau, which collects the customs trade data, does not report separate information for publicly-listed firms. We thus infer public firms’ contribution to total US exports using the following estimates: approximately 70% of listed firms (i.e., approximately 2,000 firms) are exporters, and the top 2,000 exporters in the US contribute 80% of the value of exports. Assuming that the largest exporters are also publicly listed, we arrive at our final value of 80%. A more conservative assumption that the top 500 exporters in the US are publicly listed (and *none* of the other publicly listed firms are exporters) generates a value of 60%.

Table 1: Summary Statistics

	Mean	Std. Dev.	p25	Median	p75
EXIM	0.05	0.22	0.00	0.00	0.00
Exporter	0.73	0.44	0.00	1.00	1.00
Total revenues	3,946.31	17,142.27	49.62	430.18	2,085.41
Employees	12.29	56.94	0.16	1.37	7.08
Tangible Capital	2,720.56	15,032.01	17.93	172.72	1,040.00
Intangible Capital	2,483.42	11,337.79	43.25	243.15	1,123.51
Total assets	4,754.64	19,424.28	68.31	489.75	2,360.14
Share foreign sales	0.26	0.28	0.00	0.17	0.45
MRPK	4.28	5.02	1.14	2.51	4.91
Profit margin	-0.45	1.58	-0.05	0.06	0.13
ROA	-0.05	0.29	-0.05	0.06	0.11
Dividend intensity	0.11	3.26	0.00	0.00	0.11
Leverage	0.29	0.29	0.03	0.22	0.44
Observations	28,468				

Notes: This table presents summary statistics for the main firm sample. The EXIM indicator variable takes the value of 1 if a firm was supported by an EXIM loan before the lapse in its authorization (July 1st 2015). Total revenues, Employees, Tangible Capital, Intangible Capital, and Total assets are reported in thousands. Profit margin is operating income (income before extraordinary items plus depreciation and amortization) over total revenues. ROA is EBITDA over assets. Dividend intensity is dividends over EBITDA. Leverage is long-term debt plus debt in current liabilities divided by total assets. Variables that are calculated as ratios are winsorized at the 5% level.

a log-level specification, and it removes the need for a unit fixed effect.¹⁸

Our estimation includes the relevant control group of countries o that have similar export patterns to the US (e.g., Autor, Dorn and Hanson, 2013; Hombert and Matray, 2017).¹⁹ Including these countries allows us to absorb unobserved demand shocks with product-destination-year fixed effects ($\gamma_{p,d,t}$) and exporter supply shocks with origin-year fixed effects ($\delta_{o,t}$).

EXIM dependency $EXIM_{p,o}$ is defined as the amount of EXIM financing a product received over 2007–2010, scaled by export flows in that product:

$$EXIM_{p,o} = \sum_{t=2007}^{2010} \sum_{i \in p} EXIM_{i,o,t} / \sum_{t=2007}^{2010} Export_{p,o,t}$$

where i denotes an individual EXIM contract and p denotes an HS-4 product. Since EXIM is a US institution, $EXIM_{p,o}$ is by definition always equal to zero for non-US exporters ($EXIM_{p,o} = 0$ for $o \neq US$). Figure 2 plots the distribution of treatment intensity across 3-digit industries in the US, which shows substantial variation across sectors.

¹⁸For example, the log-levels specification with a unit fixed effect (country-product μ_{po}) would take the form: $\log(Export_{p,o,d,t}) = \sum_{k=2010, k \neq 2014}^{2019} \beta_k [EXIM_{p,o} \times \mathbb{1}(t = k)] + \gamma_{p,d,t} + \delta_{o,t} + \mu_{p,o} + \varepsilon_{p,o,d,t}$. First differencing relative to the reference year 2014 eliminates the unit fixed effect: $\log(Export_{p,o,d,t}) - \log(Export_{p,o,d,t=2014}) = \sum_{k=2010, k \neq 2014}^{2019} \beta_k [EXIM_{p,o} \times \mathbb{1}(t = k)] + \gamma_{p,d,t} + \delta_{o,t} + \varepsilon_{p,o,d,t}$. The dependent variable can equivalently be expressed as $\log(\frac{Export_{p,o,d,t}}{Export_{p,o,d,t=2014}})$, which is a growth rate that we can abbreviate as $\Delta^{2014} Export_{p,o,d,t}$.

¹⁹The list of countries includes: Australia, Denmark, Finland, Germany, the UK, Japan, New Zealand, Spain, and Switzerland. Appendix Table A.2 provides robustness when we define similar countries based on their export patterns prior to 2014 by using the cosine similarity of the vector of their export market shares across product-destinations.

Figure 2: EXIM Financing Intensity by Industry (%)

Notes: This figure plots the intensity of EXIM support (EXIM financing in dollars scaled by US exports in dollars) at the NAICS-3 level for all industries that received at least one dollar from EXIM over the period 2007–2010.

We use the pre-shutdown cross-sectional variation in EXIM dependency ($EXIM_{p,o}$) to capture the supply shock to each product rather than the realized change during the shutdown.²⁰ Pre-period exposure was determined before the political shock and is plausibly exogenous to post-2015 export dynamics, whereas the realized change is potentially endogenous to outcomes. Our estimates are therefore intent-to-treat (ITT) effects, which recover the causal effect of treatment assignment even when the shutdown is incomplete (e.g., [Imbens and Rubin, 2015b](#)).

The dependent variable aggregates US firms within each product-destination cell:

$$\text{Export}_{p,d,t}^{\text{US}} = \sum_i \mathbb{I}\{\text{Backed}_i\} \cdot \text{export}_{i,p,d,t} + \sum_i \mathbb{I}\{\text{Not Backed}_i\} \cdot \text{export}_{i,p,d,t},$$

where $\mathbb{I}\{\text{Backed}_i\}$ equals one if US firm i received EXIM financing prior to 2015 and zero otherwise. Within-cell business stealing among US firms therefore nets out by construction so that the sequence of β_k coefficients captures the policy object of interest: the impact on overall US exports by industry, net of market share reallocation between firms.

To quantify the overall magnitude of EXIM’s shutdown effect on exports, we estimate a pooled regression that combines the dynamic effects:

$$\Delta^{2014} \text{Export}_{p,o,d,t} = \beta EXIM_{p,o} \times \text{Post}_{t \geq 2015} + \gamma_{p,d,t} + \delta_{o,t} + \varepsilon_{p,o,d,t} \quad (8)$$

Throughout, we cluster standard errors at the HS-4 product-level.

²⁰ $EXIM_{p,o}$ aggregates exposure across *all* EXIM products, reflecting that firms financed under one program could have shifted to others absent the shutdown. While it is theoretically possible to estimate the impact of each EXIM program separately, doing so would require having as many instruments as programs. In Appendix [Table A.6](#), we show that the estimated effects are very similar for each broad category of support (loans and insurance), although we do not interpret these as separate mechanisms given firms’ ability to substitute across programs.

Accommodating entry and exit in the trade data. Our specification requires using annual export data disaggregated by product and destination to absorb demand shocks ($\gamma_{p,d,t}$). These export markets exhibit substantial entry and exit. These changes on the extensive margin create zeros in the data, which raise challenges when estimating regressions in growth rates.²¹

We overcome these challenges by using the methodology introduced by [Beaumont, Matray, Tu and Xu \(2026\)](#) that relies on value-weighted regressions in which we measure the dependent variable $\Delta^{2014}Y_{p,o,d,t}$ as a midpoint growth rate:

$$\Delta^{2014}Y_{p,o,d,t} = \frac{Y_{p,o,d,t} - Y_{p,o,d,t=2014}}{[Y_{p,o,d,t} + Y_{p,o,d,t=2014}] \times 0.5}$$

We implement this methodology by creating a balanced panel of every export market (product-destination) present at any point during the sample period, filling missing observations, which reflect changes to the extensive margin, with zero.

[Beaumont, Matray, Tu and Xu \(2026\)](#) shows that this methodology has two important and appealing properties: First, it captures the full causal elasticity along both intensive and extensive margins by handling entry and exit without ad hoc log transformations or non-linear estimators. Second, with proper regression weights, the coefficients at any coarser level disaggregate exactly to finer levels.²² This “disaggregation invariance” is important in our setting because while entry and exit are absent at the HS-4 product level for the US, they are substantial at the HS-6-by-destination level, and this estimator ensures that the disaggregated and aggregated estimates are consistent.

Industry-level identifying assumptions and threats to identification. Our identifying assumption is that products that received more EXIM financing in the pre-period were not subsequently differentially exposed to unobserved shocks specific to the US that are correlated with a product’s EXIM dependency, conditional on the rich set of fixed effects. This identifying assumption does not require random assignment of EXIM financing, nor does it require that products have similar characteristics in levels. Rather, we rely on the standard parallel trends assumption that outcomes for treated and control would have evolved similarly absent the shutdown.

A threat to identification in the baseline equation with no additional fixed effects would be that products that receive more EXIM financing face demand shocks or changes in exporting risks when selling to specific countries. For example, a country may levy a tariff on products that receive more EXIM financing in the US. An important advantage of the bilateral product data is that it allows us to control for such confounders (which would be absorbed by $\gamma_{p,d,t}$) at a granular level, so that we only compare the exports of the same HS-6 product to the same destination at the same time.

²¹While transformations of the log function have been used to accommodate zeros (e.g., $\log(x+1)$ or the arcsine-log function), they can lead to biased estimates because they are sensitive to small variations around zero and are not invariant to the unit measurements for a value ([Cohn, Liu and Wardlaw, 2022](#); [Chen and Roth, 2024](#)).

²²[Fonseca and Matray \(2024\)](#) provides more details and an application to firm entry/exit across cities and industries.

Differences in the estimated β with and without these controls are informative about the extent to which such unobserved demand shocks might bias the estimates.

The remaining threat to identification is an unobserved shock to US products that correlates with EXIM exposure and occurs exactly when EXIM shuts down. Including a US-product-by-year fixed effect would relax the identifying assumption and allow us to capture the first direct impact of EXIM’s shutdown. While that is not possible with country-product data because our treatment varies by US-product-by-year, the firm-level bilateral exports analysis that we outline next uses firm-level exposure and thus creates variation in EXIM dependence within a given product. We can therefore fully saturate the specification with exporter-by-product-by-destination-by-year ($\zeta_{p,o,d,t}$) fixed effects and absorb all unobserved demand shocks that are specific to US exporters. In our analysis of overall firm-level effects, we can similarly include US industry-by-year fixed effects.

4.2.2 Firm-level Effects

At the firm level, we estimate event study regressions of the following form:

$$\Delta Y_{i,j,t} = \sum_{k=2010, k \neq 2014}^{2019} \beta_k \left[EXIM_i \times \mathbb{1}(t = k) \right] + \gamma_{j,t} + Exporter_{i,t_0} \times \delta_t + X_{i,t_0} \times \delta_t + \varepsilon_{i,j,t} \quad (9)$$

where $\Delta Y_{i,j,t}$ is the growth rate of various firm outcomes for firm i in industry j at time t relative to the year 2014.²³ $EXIM_i$ is an indicator variable that takes the value of one if firm i received support from EXIM during the pre-shutdown period. β_k captures the yearly semi-elasticity of firm outcomes with respect to EXIM trade financing relative to 2014.

The standard difference-in-difference is estimated using the following specification:

$$\Delta Y_{i,j,t} = \beta EXIM_i \times Post_t + \gamma_{j,t} + Exporter_{i,t_0} \times \delta_t + X_{i,t_0} \times \delta_t + \varepsilon_{i,j,t} \quad (10)$$

As in equation (7), we do not include time invariant unit fixed effects (firms in this case) because the dependent variables are measured in differences. This strategy ensures that we remove time-invariant heterogeneity across firms, which accounts for possible ex-ante differences in characteristics between treated and control firms. Industry-by-year fixed effects $\gamma_{j,t}$ restrict the identifying variation to comparing firms within the same industry each period and control for time-varying unobserved heterogeneity across US industries, such as differences in industry cycles or shocks correlated with industry-level EXIM exposure.

$Exporter_{i,t_0}$ is an indicator variable that takes the value of one if firm i reported positive EXIM

²³At the firm level, we do not need to accommodate entry and exit so we use a standard growth rate defined as $(Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. All growth rates are winsorized at the 5% level. We show the results are very similar when we use the midpoint growth rate and when we winsorize outliers in different ways in Appendix Table A.7.

trade financing, foreign sales in Compustat Segment, international activity in their 10-Ks (Hoberg and Moon, 2017), exports in Datamyne, or taxable foreign income over the pre-shutdown period. $Exporter_{i,t_0} \times \delta_t$ restricts the identifying variation to firms that would be eligible for EXIM financing and are exposed to similar worldwide aggregate demand shocks. Because this vector of fixed effects ensures that EXIM-dependent exporters are compared to a set of non-dependent exporters, the identifying variation is the same as that from dropping firms that were not exporting prior to 2015 from the sample.²⁴ $X_{i,t_0} \times \delta_t$ is a vector of firm characteristics defined prior to 2015, where each characteristic is separately interacted with year fixed effects. We cluster standard errors at the level of the shock, which is at the firm-level.

Figure 3 shows that treated and control firms are very similar along most observable dimensions. We plot the average (normalized) differences and confidence intervals at the 95% and 99% levels for various observable ex-ante characteristics. These differences are estimated unconditionally, conditional on exporter fixed effects, and conditional on industry and exporter fixed effects.

Unconditionally, treated and control firms are different, which is to be expected given that, by definition, only exporters are eligible for EXIM support. Once we include exporter fixed effects, the difference between treated and control firms for most variables is statistically insignificant at conventional levels (the red bars), with the exception of total revenues. Including industry fixed effects, as we do in our baseline specification, yields point estimates for the standardized differences that are almost equal to zero (the blue bars) and are well below the threshold for covariate balance of 0.20 recommended by Imbens and Rubin (2015a).

Along the only remaining significantly different dimension of firm size, treated and control firms still share a large overlap, which ensures that effects can be identified across firms of similar size. In addition, treated and control firms are similar in terms of their share of foreign sales and financing frictions proxied by their leverage and dividends intensity (dividends over EBITDA), growth rates of their sales and investment intensity (both in terms of physical investment and R&D), and ROA.

Firm-level identifying assumptions and threats to identification. Our identifying assumption is that there is no unobserved shock to EXIM-supported firms, conditional on the rich set of controls, that would impact their outcomes after 2015. As before, we do not need random assignment for EXIM support nor similarity in levels between EXIM-backed and non-backed firms.

Including additional control variables, such as firms being in the same industry-geography and a battery of firm characteristics (size, balance sheet metrics, lobbying activities, government contract dependency) interacted with time fixed effects, absorbs the impact of unobserved shocks correlated with these characteristics. For example, including total asset tercile-by-year fixed effects ensures that our coefficient of interest β is not driven by differences in time-varying unobserved shocks

²⁴We report this exercise in column 5 of Table 3 and show the point estimate and standard error are the same as when we use the full sample.

Figure 3: Firm Covariate Balance

Notes: This figure shows coefficient estimates and 95% (darker bars) and 99% (lighter bars) confidence intervals of the difference between treated and control firms for different variables. All variables are normalized to have a mean of zero and a standard deviation of one, and ratios are winsorized at the 5% level. “Unconditional” refers to the sample comparing treated firms to all untreated firms without conditioning on any fixed effects. “Exporter” indicates that the firm has either received EXIM support, reported foreign sales in Compustat Segment, has international activity in its 10-Ks, has positive exports in Datamyne, or reports taxable foreign income. “Industry” is defined at the SIC2 level. Leverage is defined as total debt over assets, revenue growth is the computed over 2010–2014, ROA is defined as EBITDA over assets, total capital is computed as the sum of property, plants and equipment and intangible capital measured by [Peters and Taylor \(2017\)](#).

affecting firms of different sizes, effectively matching firms within comparable size categories. Similarly, controlling for lobbying behavior matches firms with similar political engagement, ensuring that the estimated effects are not attributable to shocks to the value of political connections.

Our approach of controlling flexibly for observable characteristics acts similarly to propensity score matching, but with notable advantages: it maintains transparency, preserves the full sample without dropping observations, and accommodates non-parametric relationships between covariates and outcomes rather than imposing linearity assumptions typical in matching methods.

5 Average Effects of EXIM’s Shutdown

Our first set of results examines whether EXIM trade financing creates US exports. In the aggregate, we find that EXIM’s exit led to a sizable decline in exports of products that received more financing prior to the shutdown. We then show how this contraction in foreign sales also lowered average firm exports, total revenues, investment, and hiring.

5.1 Average Effects on Exports

We begin by estimating equation (8) at various levels of aggregation. We weight the regressions using the value of the denominator of the midpoint growth rate in the origin-product (HS-4)-year cell to capture the effect of EXIM’s shutdown on aggregate exports by product.²⁵

Table 2 reports the results. Columns 1–3 demonstrate the aggregation property of the method developed in Beaumont, Matray, Tu and Xu (2026) and show that the estimated β recovers exactly the same point estimate and standard errors whether we work at the origin $\times$ (HS-4) product level, the origin $\times$ (HS-6) product level, or at the origin $\times$ (HS-6) product $\times$ destination level, as long as we include the same set of fixed effects and weight the regressions appropriately.²⁶ The value of -4.49 means that a \$1 change in EXIM trade financing generates a change of -\$4.49 in total US exports at the product level.

Column 4 adds (HS-6) product $\times$ year fixed effects while column 5 adds (HS-6) product $\times$ destination $\times$ year fixed effects. In this last case, we identify the effect of EXIM’s shutdown by comparing different origin countries exporting exactly the same finely classified product to the same country at the same time. The point estimate is stable and if anything slightly larger and more significant after controlling for market (destination-product) specific shocks (-4.49 in column 1 vs -5.13 in column 5). The stability in the point estimates implies that the exposure to EXIM is uncorrelated with product-by-destination specific demand and risk shifters. In column 6, the coefficient indicates that EXIM’s shutdown reduces exports of products highly exposed to EXIM funding relative to less exposed products by 6.1%. The average EXIM support for the group of products with exposure above 0.45% is approximately 1%, which implies an effect of -6.2 (-6.1%/1%). Econometrically, the similarity in magnitude with our estimate of -5.13 (column 5) means that a linear effect of the dosage treatment is a reasonable approximation that, if anything, underestimates the true effect of EXIM’s shutdown on total exports.

In Figure 4, we plot the yearly point estimates and the 95% confidence intervals of the annual event study from equation (7). There are no differential pre-trends prior to the shock, and exports then decline progressively throughout the period of EXIM’s shutdown, with only a slight reduction in the gap in the last year, when EXIM regains its full status. Following standard event-study practice (e.g., Autor, 2003; Marcus and Sant’Anna, 2021), we formally test the plausibility of

²⁵Due to the granularity of the distribution of export values, the law of large numbers may no longer apply, which creates an inference problem when using such weighting. We address this issue by winsorizing the extreme values of the weights at 5%, and we report the robustness of the results when we equal weight the data, winsorize at 1%, or use time-invariant weights in Appendix Table A.3.

²⁶The number of observations reflects the increasing granularity of the data. Weights are computed in the following way: Define $A_{o,p,d,t} = (Y_{o,p,d,t} + Y_{o,p,d,t=pre}) \times 0.5$. At the origin $\times$ HS-6 $\times$ destination $\times$ year, each cell is weighted by: $A_{o,hs6,t} / (\sum_{hs6 \in [o,hs4,t]} A_{o,hs6,t})$, which guarantees that the equation provides an equal weighting at the origin $\times$ HS-4 $\times$ year level. We then multiply this weight by $A_{o,p=hs4,t}$ to preserve the definition of β as measuring the effect of EXIM on aggregate exports.

Table 2: EXIM’s Shutdown Reduces US Product Exports

Dependent variable Level of aggregation	Exports					
	HS-4	HS-6	HS-6×Destination	HS-6×Destination		
	(1)	(2)	(3)	(4)	(5)	(6)

Product (HS-6)×Year	—	—	—	✓	—	—
Product (HS-6)×Destination×Year	—	—	—	—	✓	✓
Observations	109,208	8,541,850	24,143,761	24,143,761	24,143,761	24,143,761

Notes: This table reports estimates on the effect of EXIM’s shutdown on aggregate exports at the product-by-destination level taken from BACI. The dependent variable is the exports growth rate of origin country o (exporter) to destination country d (importer) of product p at time t relative to 2014 (the year prior to the shock), and is defined as $\Delta Y_{p,o,d,t} = (Y_{p,o,d,t} - Y_{p,o,d,2014}) / [(Y_{p,o,d,t} + Y_{p,o,d,2014}) \times 0.5]$. The sample includes a control group of other exporter countries o with similar export patterns as the US. EXIM intensity (EXIM_{po}) in columns 1-5 is defined as the total amount of EXIM (in \$) over total exports (in \$) over the period 2007–2010. In column 6, EXIM_{po} ≥ 0.45% is an indicator variable for a product being in the top quartile of treatment value. Products are defined by the standard trade classification Harmonized System (HS) code. In columns 1–3, the coefficients and standard errors are identical by construction of the midpoint growth estimator (Beaumont, Matray, Tu and Xu, 2026). Standard errors are clustered at the HS-4 level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

the parallel-trends assumption by estimating whether the pre-treatment event-time coefficients are jointly equal to zero. The joint F -statistic is 0.24 (p -value = 0.915), implying we cannot reject the null that the pre-treatment coefficients are jointly zero, consistent with parallel pre-trends.

The primary threat to identification is that demand shocks are exporter-by-product specific (i.e., at the level of $\zeta_{p,o,t}$). However, such a demand shock is unlikely to explain our results for several reasons. First, the “trade war” between China and the US did not begin until 2018, well after the exports of EXIM-dependent products began to decline (Figure 4). Second, Appendix Figure B.1 and Figure B.1 report leave-one-out distributions of point estimates and t -statistics, sequentially excluding each 3-digit product or destination. The estimates remain tightly centered around the baseline effect in Table 2, indicating that the results are not driven by a small number of products or destinations exposed to contemporaneous shocks.

Third, we further address concerns about demand-side confounders using firm-level evidence from Datamyne bills-of-lading data, which records maritime exports at the firm-by-product-by-destination level. Because the comparison is between US exporters shipping the same HS-6 product to the same destination, country-specific tariff shocks (e.g., the 2018–19 China tariffs on certain US products) and other unobserved product-destination demand shocks are absorbed by fixed effects, so the analysis does not rely on the industry-level identifying assumption. Appendix Table A.4

reports the results. The point estimate of -0.12 implies an average impact of -3.4 on export sales, similar in magnitude to the aggregate product-level estimate.

Figure 4: Event Study of Impact of EXIM’s Shutdown on US Product Exports

Notes: This figure plots the point estimates and 95% confidence intervals of the effect of EXIM’s shutdown on aggregate exports at the product (HS-6)-by-destination level from the event study defined in equation (7) with product-destination-year and origin-year fixed effects. The dependent variable is the exports growth rate of origin country o (exporter) to destination country d (importer) of product p at time t relative to 2014 (the year prior to the shock), and is defined as $\Delta Y_{p,o,d,t} = (Y_{p,o,d,t} - Y_{p,o,d,2014}) / [(Y_{p,o,d,t} + Y_{p,o,d,2014}) \times 0.5]$. The sample includes a control group of other exporter countries o with similar export patterns as the US. EXIM intensity ($EXIM_{po}$) is defined as the total amount of EXIM (in \$) over total exports (in \$) over the period 2007–2010. Standard errors are clustered at the HS-4 product level. The F -statistic estimating whether the pre-treatment event-time coefficients are jointly equal to zero (e.g., [Autor, 2003](#); [Marcus and Sant’Anna, 2021](#)) is 0.24 (p -value = 0.915).

Interpretation of magnitudes. Because $EXIM_{p,o}$ and $\Delta^{2014} Export_{p,o,d,t}$ are both normalized by pre-shutdown export values, β is the *dollar pass-through* of EXIM financing to US exports. The coefficients estimated in [Table 2](#) are between 4 and 5, implying that a \$1 contraction of financing reduces export revenues by \$4–5. This is an *export revenue* elasticity, not a *return* elasticity: the magnitude of 4.49 should not be read as a return on EXIM lending.

The magnitude is consistent with the working-capital intensity of exporting. Producing and shipping foreign sales requires roughly \$0.20–0.25 of working capital per dollar of revenue, reflecting the inputs, inventories, and payment delays standard in international trade.²⁷ Relaxing \$1 of a binding financing constraint can therefore support approximately \$4–5 of additional export sales. Because EXIM support can complement internal liquidity, private credit, and trade credit, the coefficient captures the reduced-form effect of relaxing the overall financing constraint on exporting.

Possible SUTVA violation. By construction, our baseline specification accounts for all types of business stealing that could happen across firms or across destinations within the same HS-4. To test for higher level of possible spillovers (positive or negative), we follow the strategy recommended in [Beaumont, Matray, Tu and Xu \(2026\)](#) and re-estimate our specification across different levels

²⁷For exporters in Compustat, the ratio of working capital (receivables plus inventories) to total revenues averages 27%; the BIS estimates a similar 30% ([Committee on the Global Financial System, 2014](#)).

of aggregation, from HS-6 to HS-2. As we use coarser aggregation levels, more of the across-firm reallocation within a product category is netted out. Across all levels, we find that the coefficient remains virtually unchanged (Appendix Table A.1), suggesting that EXIM was mostly creating net additional trade for the US.

5.2 Average Effects on Firm Outcomes

The results above reject two hypotheses about EXIM support: (a) that such support is just infra-marginal, and thus has no effect on exports, and (b) that it merely reallocates market share across US firms, and thus does not affect overall product-level exports. Nonetheless, it is still possible that the shutdown had limited effects on firm investment and employment if EXIM-backed firms were able to compensate for the loss of their exports by increasing domestic sales.

5.2.1 Effect on Total Revenues

Baseline effect. To test whether the shutdown and contraction in exports affect firms’ total revenues, we begin by estimating the β coefficient in equation (10) that captures the average change in total revenues for EXIM-backed relative to non-backed firms over the post period (2015–2019) relative to the pre-period.²⁸ Table 3 reports our results. Column 1 is estimated with the sparsest set of controls: only year fixed effects. Column 2 includes industry-by-year fixed effects to account for the potential correlation between the treatment exposure and unobserved industry shocks (e.g., differential demand shocks). Column 3 is our preferred specification that includes both industry-by-year and exporter-by-year fixed effects, with the latter controlling for the correlation between the treatment and other trade-related shocks.

The estimated effect on total revenues is stable across the different set of controls and is always significant at the 1% level, ranging from a difference of 17% in column 1 to 12% in column 3.

In columns 4 to 8, we conduct additional robustness exercises. Column 4 includes a battery of additional firm-level controls: the fiscal month of firms’ reporting of their annual accounts, firm size (terciles of total assets), firm leverage and profitability, and firm lobbying expenditure (measured using Lobbyview data), all interacted with year fixed effects.

Columns 5 to 7 show that the effect of EXIM’s shutdown is not driven by certain parts of the sample and remains quantitatively similar whether we exclude: non-exporting firms (column 5), the ten firms with the highest pre-period reliance on EXIM support including Boeing (column 6),²⁹

²⁸For all the D-i-D analyses, we weight the regressions by firm revenue using the same strategy as in the aggregate product exports data to ensure comparability of the results across datasets. The coefficients are, if anything, larger with other weighting schemes or no weights: see Appendix Table A.8.

²⁹While EXIM authorizations are skewed in dollar value because of differences in firm size and transaction scale (the top 10 recipients account for 64.7% of total authorized amounts by dollar value, with Boeing alone accounting for 34.0%), this skewness does not mechanically drive our firm-level treatment because $EXIM_i$ is an indicator for whether

or all industries that are in the top tercile of dependence on government spending (column 7). The fact that the point estimate remains unaffected indicates that the effect is not driven by a broader shock on government spending that would affect firms more dependent on such spending, but instead is specific to EXIM’s shutdown.

Finally, in column 8, we estimate a triple difference where we interact the D-i-D variable with an indicator variable that takes the value of one if the firm received a large loan from EXIM prior to its shutdown, which acts as a proxy for firms’ likelihood of depending on large loan financing. We define large loans as those in the top tercile of the loan distribution, and we interact all the fixed effects with an indicator variable for the firm receiving any EXIM loan prior to the shutdown.

In this exercise, the coefficient of interest is estimated *within* EXIM-dependent firms as the EXIM-by-year fixed effect controls for any time-varying unobserved shocks specific to all EXIM-dependent firms.³⁰ The coefficient and standard error remain nearly identical to the baseline effect that we estimate in column 3, indicating that our results are unlikely to be driven by endogenous selection of firms receiving EXIM financing.

Figure 5 plots the yearly coefficients of β_k and 95% confidence intervals of the growth of total revenues relative to 2014 for the dynamic event study in equation (9), controlling for the full set of firm characteristics (industry, exporter status, size, leverage, profitability). The F -statistic for joint significance of the coefficients in the pre-period is 0.22 (p -value = 0.926), supporting our visual assessment of parallel trends. Appendix Figure B.3 reports robustness for the firm event study when we progressively include the different fixed effects and firm controls, and it transparently shows that the point estimates are barely affected as we control for more unobserved heterogeneity. Appendix Figure B.4 shows the event study in the quarterly data, which allows us to define the shock *within* 2015. As in our baseline specification, there are no differential pre-trends and the divergence between treated and control firms begins in the first observable time period after the shutdown, in this case the third quarter of 2015.

This persistent decline in total revenues implies that treated firms are not able to (i) fully compensate for the loss of foreign sales by an increase in domestic sales, and (ii) compensate for the loss of EXIM financing with trade financing at commercial, profit-maximizing banks.

Interpretation of magnitudes. The coefficient of -0.12 (column 3) implies that shutting down EXIM lowers total revenue by 12%. On average, EXIM financing amounted to 2.4% of total revenues for treated firms, so a one dollar reduction in EXIM financing lowered treated firms’ total revenues by \$4.9 ($12\%/2.4\% = 4.9$). Since the dollar pass-through on foreign sales is about \$4.5 (Tables 2

a firm received any pre-shutdown EXIM support rather than a dollar-weighted measure of authorizations. The list of top 10 recipients also includes: Cytosorbents Corp, Energy Recovery Inc, Everspin Technologies Inc, Full Spectrum Inc, Impinj Inc, Mycelx Technologies Corp, Optical Cable Corp, Stereotaxis Inc, and Xtera Communications Inc.

³⁰The primary D-i-D coefficient $EXIM \times post$ is no longer identified, as it is now collinear with the fixed effects.

Notes: This table reports the estimated effects of EXIM’s shutdown on firms’ total revenue growth. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, international activity in their 10-Ks, exports in Datamyne, or taxable foreign income before 2014. Industries are SIC-2. Column 5 excludes firms that are not exporting prior to the shutdown, and column 6 removes the top ten recipients of EXIM support in the pre-period. Column 7 removes industries that are most dependent on government policies, which we construct by regressing monthly stock returns for each industry on the measure of policy uncertainty specifically related to government policies and fiscal policies from Baker, Bloom and Davis (2016). Finally, in column 8 we interact $EXIM \times Post$ with an indicator variable *Large loans* that takes the value one if the support was in the top tercile of EXIM’s financing distribution prior to its shutdown, as these firms were particularly affected by the loss of the bank’s board quorum. We interact $EXIM$ with exporter-by-year and industry-by-year, in which case $EXIM \times Post$ is no longer identified. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

and 3) and using the accounting identity that $\Delta TotalRevenues = \Delta Exports + \Delta Domestic$, we can deduce that the EXIM-driven reduction in foreign sales had if anything a *negative* effect on domestic sales by approximately \$0.50. Appendix D.1 shows that we can estimate this positive elasticity between foreign and domestic sales to be between 2.8% and 7.5%.

Implication for firm production functions and comparison with the literature. Positive spillovers between foreign markets and the domestic market are at odds with the canonical Melitz (2003) model of firm-level trade that features constant marginal cost, in which demand shocks in one market do not affect a firm’s sales in another. These results are instead consistent with models of intra-firm spillovers, which can emerge from knowledge transfers (e.g., Ding, 2024), vertical supply linkages (e.g., Desai, Foley and Hines, 2009; Boehm, Flaaen and Pandalai-Nayar, 2019), or financing frictions and internal capital markets (e.g., Lamont, 1997; Giroud and Mueller, 2019).

Our findings are particularly likely to reflect the role of internal capital markets because EXIM designs its program to service financially constrained firms (Table D.4 and Appendix Section C.4).

Figure 5: Event Study Impact of EXIM’s Shutdown on Firm Total Revenues

Notes: This figure plots the point estimates and 95% confidence intervals of the effect of EXIM’s shutdown on firm total revenues from equation (9) with industry-by-year and exporter-by-year fixed effects. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. Standard errors are clustered at the firm level. The F -statistic estimating whether the pre-treatment event-time coefficients are jointly equal to zero (e.g., [Autor, 2003](#); [Marcus and Sant’Anna, 2021](#)) is 0.22 (p -value = 0.926).

When firms face financing constraints and use internal capital markets to finance projects across different markets, theory predicts positive spillovers between markets [Stein \(1997\)](#). In our context, the reduction in exports acts as a negative cash flow shock for treated firms, tightening their financing constraints and affecting their domestic sales.

Additional robustness. We conduct several additional robustness checks showing results are not driven by specific firms or industries. Appendix [Figure B.2](#) reports coefficients and t-statistics from 336 regressions excluding each 4-digit industry individually, which cluster tightly around the average values in [Table 3](#) and [Figure 5](#), showing that no single industry drives the results. Appendix [Table A.5](#) shows that more granular industry fixed effects yield similar results.

5.2.2 Effect on Additional Firm Outcomes

Given that EXIM-financed firms experience a decline in total revenues after EXIM’s exit, it is likely that the shutdown also affects the accumulation of production factors (capital and labor). We use the specification in equation (10) and replace firm revenue growth with firms’ change in capital, labor, and operating profit margins (EBIT over revenues).

[Table 4](#) shows that EXIM’s shutdown reduced both investment and hiring. Intangible capital shrinks slightly more than tangible capital (-19% vs -14%), in line with intangible capital being more sensitive to financing frictions and therefore fluctuating more with firm revenues (e.g., [Hombert and Matray, 2017](#)). Column 4 shows the effect for employment. In contrast, profit margins remain

Table 4: Impact on Firm Employment, Capital Accumulation, and Profit Margins

Notes: This table reports the estimated effects of EXIM’s shutdown on various firm outcomes. Intangible capital is measured following [Peters and Taylor \(2017\)](#). Tangible capital is “property, plants, and equipment.” Profit margin is measured as net income over revenues. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, international activity in their 10-Ks, exports in Datamyne, or taxable foreign income before 2014. Industries are SIC-2. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

unaffected: the economically small and statistically insignificant estimate (column 5) indicates EXIM financing did not artificially inflate profit rates before the shutdown. Appendix [Figure B.5](#) presents event studies for each outcome.

6 Impact on Capital Allocation

Our results so far show that EXIM financing was not inframarginal on average, and instead enabled new economic activity prior to the shutdown. We now assess how EXIM financing affected the allocation of capital across firms.

The model gives a sharp prediction resting on two premises. By [Proposition 2](#), withdrawing pledgeability support raises capital misallocation provided (i) the shock operates through firm-specific financing constraints rather than the common risk-adjusted cost of capital r_x^{adj} , so that more-constrained, high-MRPK firms respond more ([Proposition 1](#)); and (ii) support is not skewed toward low-MRPK firms ($\rho \geq 0$, [Lemma 2](#)). We establish each premise in turn.

6.1 Estimating Changes in Misallocation in the Data

We begin by estimating the differential within-firm response across high and low MRPK firms.

6.1.1 Empirical strategy

Measuring MRPK. To bring the model to the data, we assume firms have Cobb-Douglas revenue production functions, $Revenue_{ijt} = TFPR_{ijt} K_{ijt}^{\alpha_j^k}$, where i , j , and t index firm, industry, and year.

In this case $MRPK = \alpha_j^k Revenue_{it}/K_{it}$, so $Revenue_{it}/K_{it}$ provides a within-industry measure under the assumption that all firms in an industry share the same capital share α_j^k .³¹

Two concerns separate this measure from the model object: a measurement issue in the cross-section of MRPK *levels*, and a threat to identification in how firms *respond* to the shutdown.

The measurement issue is that a cross-section of MRPK levels does not isolate financing-constraint dispersion. From the model’s first-order condition (Equation 5), $\log MRPK_{i,x} = \log r_k + \log(1 + \tau_{i,x})$, where the wedge $\tau_{i,x}$ loads on both the market-level risk-adjusted return r_x^{adj} and the firm-specific shadow price λ_i , so cross-firm MRPK dispersion conflates differences in λ_i with differences in r_x^{adj} and measurement error.³² We mitigate this issue by sorting firms into progressively narrower cells: SIC-4 industries; SIC-4 $\times$ pre-period size quartiles, where size is firm employment (using employment rather than assets avoids a mechanical correlation between MRPK and capital from measurement error); and SIC-4 $\times$ size $\times$ risk quartiles, where risk is the CAPM beta computed from monthly returns prior to 2015. Each step absorbs more between-cell variation that is common across comparable firms but unrelated to firm-specific constraints, so the remaining within-cell MRPK dispersion more plausibly reflects λ_i .

More fundamentally, our identification comes from within-firm changes rather than from the cross-sectional level of MRPK. To estimate the within-firm response to the EXIM shutdown for constrained and unconstrained firms, we implement the [Bau and Matray \(2023\)](#) triple-difference specification:

$$\begin{aligned} \Delta^{2014} K_{i,j,t} = & \beta_1 EXIM_i \times Post_{t \geq 2015} \times H_i^{MRPK} \\ & + \beta_2 EXIM_i \times Post_{t \geq 2015} \\ & + \Gamma_{i,j,t} + H_i^{MRPK} \otimes \Gamma_{i,j,t} + \varepsilon_{i,j,t}, \end{aligned} \quad (11)$$

where $\Delta^{2014} K_{i,j,t}$ is the growth rate of capital between year t and 2014, H_i^{MRPK} is an indicator equal to one if firm i is above the median MRPK in its pre-period sorting cell, $\Gamma_{i,j,t}$ collects the baseline fixed effects and controls (industry-by-year, exporter-by-year, and pre-period firm characteristics interacted with year), and $\otimes$ denotes their full interaction with the high-MRPK indicator, which lets high- and low-MRPK firms follow different trends within cells.

The coefficient β_2 is the capital response of low-MRPK exporters to the shutdown and β_1 is the differential response of high-MRPK exporters, the empirical counterpart of the per-unit differential in Proposition 1 and Lemma 2; the model predicts $\beta_1 < 0$.

³¹This assumption is for simplicity; the methodology accommodates any production function. Appendix [Table D.2](#) reports similar results when we estimate the production function using [Olley and Pakes \(1996\)](#), use a user-cost approach similar to [Baqae and Farhi \(2020a\)](#), or assume a more general CES production function.

³²Differences in MRPK could also reflect differences in output markups or differences in capital share if they are not industry specific. We discuss this below.

Because identification comes from within-firm *changes*, any time-invariant component of a firm’s MRPK level is differenced out and β_1 is an unbiased measure of the change in misallocation even if ex-ante MRPK only reflects firm input wedge with noise. This is a strength of our strategy that circumvents many of the classic critiques of using cross-sectional dispersion in MRPK to infer misallocation. We only require that the EXIM shock does not load differentially on unobserved characteristics that would be correlated with MRPK.

Identifying assumptions. Equation (11) is identified under the standard triple-difference assumption that, absent the shutdown, the difference between high- and low-MRPK firms would have evolved similarly for EXIM-backed and non-backed firms. An ex-post confound must therefore satisfy three conditions at once: it coincides with the shutdown in timing, loads on ex-ante EXIM exposure, and loads differentially on ex-ante MRPK.

This identifying assumption is looser than parallel trends in the baseline difference-in-differences: we do not require high- and low-MRPK firms to share a trend, since the high-MRPK indicator is interacted with the baseline fixed effects and controls, nor EXIM-backed and non-backed firms to share a trend, since we include EXIM-by-year fixed effects.

6.2 EXIM Shutdown Increases Capital Misallocation

Figure 6 provides graphical evidence by estimating the effect of EXIM’s shutdown separately for high- and low-MRPK firms. The figure shows no differential pre-trends for either group, consistent with the identifying assumption. After the shutdown, high-MRPK firms contract investment significantly more than low-MRPK firms, indicating that capital moves away from firms with high ex-ante marginal returns.

The heterogeneity in these effects provides further evidence that EXIM’s impact stems from its ability to relax financing frictions facing constrained exporters. When exporters are less constrained, and hence have lower MRPK, EXIM’s shutdown has limited effect. This muted response among lower-MRPK firms is consistent with the concern that ECA financing can be inframarginal when recipients have access to alternative sources of funding.

Table 5 shows the results from estimating equation (11). We report the outcomes when we estimate separate regressions for a sample split by MRPK (columns 1, 2, 4, 5, 7, 8) or estimate a regression in the full sample with a triple interaction (columns 3, 6 and 9). In the triple-difference regression, we directly control for $EXIM \times Year$ fixed effects such that the D-i-D coefficient $EXIM_i \times Post_t$ is not estimated.

In columns 1–3, we replicate Figure 6 by estimating the change in capital across the MRPK distribution computed within the same industry. The coefficients indicate that while low MRPK firms are barely affected by the shock (5%, not statistically significant), high MRPK firms reduce

Figure 6: EXIM’s Shutdown Amplifies Capital Misallocation

Notes: This figure plots the effect of EXIM’s shutdown on investment, estimated separately for firms with high and low MRPK, along with 95% confidence intervals. We include industry-by-size quartile-by-year, and exporter-by-year fixed effects. MRPK is computed as average revenues over physical capital between 2010 and 2013. “High MRPK” firms are firms with an MRPK value above their industry median. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. Standard errors are clustered at the firm level.

their investment by 19%, and the difference between the two groups of firms increases by 14%.³³

Columns 4–6 report the results when we adjust the measure of misallocation for differences in size, and columns 7–9 when we adjust for differences in risk using CAPM betas. In all cases, we find similar point estimates, and if anything larger magnitudes for high-MRPK firms, while low-MRPK firms continue to be largely unaffected. The stability of the misallocation estimates when controlling for risk does not imply that EXIM failed to reduce export risk; rather, any risk-reduction benefits appear to have been distributed uniformly across high- and low-MRPK firms.

Robustness. The misallocation result is robust to how we measure and sort on MRPK. Table D.2 re-estimates the triple-difference using alternative measures of the capital wedge: MRPK from an Olley and Pakes (1996) production-function estimate, the user-cost measure of Baqaee and Farhi (2020a), total-input TFPR, and CES-based input-cost ratios. The differential contraction of high-MRPK firms is similar throughout. Table D.3 instead sorts firms within SIC-4 $\times$ size $\times$ destination cells, defining a firm’s destination from its modal pre-period shipments, and the result again holds whether destination is the buyer’s or the goods’ country.

³³This asymmetric response is also why we focus on differential input changes rather than changes in the variance of TFPR. As shown in Bau and Matray (2022), changes in industry-level TFPR dispersion identify changes in misallocation only under assumptions such as joint log-normality of TFPR and TFPQ, which imply approximately symmetric responses by high- and low-MRPK firms. Our estimates show precisely the kind of asymmetric response that violates this restriction.

Notes: This table reports the estimated effects of EXIM's shutdown on firms' capital investment. MRPK is defined as average revenues over physical capital between 2010 and 2013. In columns 1–3, firms are sorted along their SIC-4 median. In columns 4–6, firms are sorted along the median of their SIC-4 × quartile of employment distribution. $I_i^{High\ MRPK}$ is an indicator that takes the value one if the firm is above the median. In columns 7–9, risk is defined as the firm returns' "equity beta" (i.e., the comovement between the firm stock price return and the market return). The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, international activity in their 10-Ks, exports in Datamyne, or taxable foreign income before 2014. Industries are SIC-2. In columns 3 and 6, all the baseline fixed effects are interacted with $I_i^{High\ MRPK}$. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

6.3 Interpreting the Differential Response

6.3.1 Evidence on the Source of the Wedge

The misallocation result above identifies high-MRPK firms as those for which capital is undersupplied, but it does not directly identify the source of the wedge. We now provide evidence that the wedges correspond to two specific frictions predicted by the institutional context of Section 2.2.1: firm-level financing constraints and destination-market contractual frictions. The convergence of the two pieces of evidence supports the interpretation that the input-cost wedge $\tau_{i,x}$ in our frame-

work reflects financing-related frictions in cross-border trade rather than unmeasured sources of MRPK dispersion such as differences in capital shares or risk-adjusted real returns.

Firm financing frictions. We use four standard proxies for ex-ante financing constraints: firm age, industry leverage, the [Hoberg and Maksimovic \(2015\)](#) text-based private-debt-delay measure, and the industry coverage ratio. For each, we sort firms into terciles and estimate a triple-difference that interacts EXIM exposure with the proxy. The shutdown’s effect on investment is consistently concentrated in the most-constrained tercile, where it is roughly twice as large as in the least-constrained tercile ([Appendix D.5](#)). The effect is also larger for firms with above-median pre-shock reliance on EXIM financing ([Appendix D.2](#)), consistent with the effects being driven by firms for which EXIM support was economically meaningful.

Destination-market frictions. Using proxies that capture distinct dimensions of the cross-border environment such as rule of law ([Kaufmann, Kraay and Mastruzzi, 2010](#)), financial development, US bank presence, and the share of state-owned banking assets ([Panizza, 2024](#)), we examine whether EXIM’s effect is concentrated in destinations with weaker contractual or financial environments. Firm-level shipments (using Datamyne bill-of-lading data) show effects that are 30 to 55% more negative in high-friction destinations than in low-friction destinations ([Appendix D.6](#)), consistent with EXIM’s institutional mandate.³⁴

6.3.2 What the asymmetry implies about the friction

The concentration of the response in high-MRPK firms, with low-MRPK firms barely responding speaks to the structure of the friction. A financing-constraint channel implies a sign-identifying moment: more constrained, high-MRPK firms respond more strongly to a change in financing access than less constrained firms, whereas a shock to the common risk-adjusted cost r_x^{adj} would affect all firms. The observed asymmetry is the former, and is inconsistent with a pure risk-adjusted-cost-of-capital interpretation.³⁵

³⁴We discuss two alternative non-financing channels in [Appendix D.5](#). First, EXIM does not run marketing or export-promotion programs, so promotional channels cannot explain our results. Second, a private-sector “wait-and-see” response is hard to reconcile with the duration of the shutdown and with the firm- and destination-level heterogeneity we document.

³⁵Whether high-MRPK firms should react at all depends on the micro-foundation of the financing friction. If the friction produces quantity rationing, as in our model and in most macro-finance models, high-MRPK firms barely react: their capital is pinned at a borrowing ceiling set by net worth and pledgeability, not by the return to capital. If the friction instead operates through the price of capital (a smooth external-finance premium that rises with leverage, as in costly-state-verification or financial-accelerator models), even constrained firms stay on an interior margin and expand by paying a higher premium, so high-MRPK firms do react, though by less than frictionless firms.

6.3.3 Combined wedge, input wedge and output markup

Dispersion in MRPK captures distortions that drive a wedge between the observed and efficient allocation of inputs. In the model, the relevant distortion is the export-financing wedge $\tau_{i,x}$; in richer environments, MRPK may also reflect heterogeneous output markups. However, this distinction is immaterial for our allocative-efficiency result: in either case, firms with high MRPK are “too small” relative to the efficient allocation, and a shock that disproportionately reduces their capital increases misallocation and lowers aggregate TFP (Hsieh and Klenow, 2009a; Restuccia and Rogerson, 2008; Baqaee and Farhi, 2020b; Edmond, Midrigan and Xu, 2023).³⁶

6.4 EXIM Policy Targeting and Aggregate Magnitude

Policy targeting. The reallocation effect depends not only on the per-unit response estimated above but also on how EXIM support was distributed across firms. We therefore assess the incidence of EXIM support directly by regressing firms’ pre-period MRPK on pre-shutdown EXIM exposure, adding increasingly saturated fixed effects for industry, exporter status, size, risk, and controlling for lobbying expenditures. The estimates are small, statistically insignificant, and if anything weakly positive.³⁷ Thus, we find no evidence that EXIM support was tilted toward low-MRPK firms. In the language of the model, the targeting covariance is approximately zero, $\rho \approx 0$, so the differential response documented above is not offset by adverse policy targeting.

This pattern is consistent with EXIM’s institutional design. Firms must first demonstrate that private financing is unavailable to them, which selects toward firms facing binding financing constraints. At the same time, EXIM is required to maintain a portfolio default rate below 2%, which limits support to firms that are financially constrained but plausibly solvent. These eligibility and governance constraints make it unlikely that EXIM support is systematically directed toward firms with slack financing constraints and low marginal returns to capital.

Aggregate magnitude. Using the Bau and Matray (2023) Solow residual decomposition, we estimate that the increase in in capital misallocation caused by the EXIM shutdown reduced aggregate TFP by -0.43 to -1.56 pp. Appendix D.3 presents the full computation and an intensity-weighted version that accounts for heterogeneity in firms’ pre-shock reliance on EXIM financing.

³⁶The pattern is nevertheless more naturally aligned with a financing-wedge interpretation. In variable-markup models, firms with greater market power tend to absorb shocks through markup adjustment and exhibit smaller quantity responses, whereas we find larger real responses among high-MRPK firms (Berman, Martin and Mayer, 2012; Amiti, Itskhoki and Konings, 2014).

³⁷Across four specifications, the coefficient on EXIM exposure ranges from 0.05 to 0.20, with p-values between 0.55 and 0.88. See Appendix Table A.9.

7 Discussion

7.1 Additional Channels for Welfare

The model’s welfare decomposition in equation (6) identifies three channels through which the partial-equilibrium gains we estimate could be attenuated at the aggregate level: a terms-of-trade decline, capital-market crowd-out of domestic production, and the fiscal cost of the program. While the first two are general-equilibrium mechanisms and cannot be fully tested, the model still delivers clear predictions about regression coefficients we can estimate to gauge the magnitude of these forces. We test each directly and find that they are small in our setting.

7.1.1 Terms-of-Trade Effects

The model’s $1 - w_x$ factor implies that part of the export-revenue gain from an ECA expansion is absorbed by a decline in the price index of Home varieties. We test this directly using BACI unit values, computed as the ratio of export value to quantity at the HS-6 product-by-destination-by-year level, and apply our baseline difference-in-differences specification with the same synthetic control group of OECD exporters as in the main analysis. Across six specifications spanning two outcome definitions (log levels and log growth rates) and three fixed-effect saturations, the coefficient on EXIM exposure is statistically insignificant and switches signs across columns (Appendix D.7.1). The absence of a price response implies that terms-of-trade considerations are not first-order in our setting, consistent with recent estimates of small US terms-of-trade elasticities (Fajgelbaum, Goldberg, Kennedy and Khandelwal, 2020; Amiti, Redding and Weinstein, 2019; Cavallo, Gopinath, Neiman and Tang, 2021; Jiao, Liu, Tian and Wang, 2024).

7.1.2 Crowding Out Domestic Producer Capital

The model also predicts that an ECA expansion raises the equilibrium rental rate of capital, which could draw inputs away from domestic production. We test this directly by examining whether revenues of non-EXIM firms expanded during the shutdown since a contraction of EXIM-backed firms lowers the domestic interest rate and could lead domestic firms to expand (Proposition 4).

We use two samples (a broad sample of all non-EXIM firms, and a stricter sample restricted to firms with zero foreign sales in the pre-period), two exposure measures (the continuous EXIM intensity of the firm’s NAICS-4 industry, and the share of treated firm sales within the industry or state), and two aggregation levels (industry and state). The estimated coefficients are small and statistically insignificant in every cell (Appendix D.7.2). Three explanations are each individually sufficient to explain this absence of spillovers: EXIM is small relative to the US economy ($\sim 1.8\%$ of US exports, $\sim 0.16\%$ of GDP); friction-relaxation unlocks rather than reallocates capital between

domestic producers and exporters, so non-EXIM firms face no crowding-out pressure; and the misallocation channel raises aggregate output through productivity rather than by drawing new inputs into the export sector.

7.1.3 EXIM Profitability

ECAs theoretically have access to tax revenues, which could allow them to operate at a loss. Reconstructing EXIM’s balance sheet from its annual reports, we find that the bank generated approximately \$480 million in profits over our sample period at a 0.3% default rate, so the fiscal-cost term in the welfare decomposition is approximately zero (Appendix C.5.1). EXIM’s ability to operate profitably while serving constrained borrowers is consistent with its institutional advantages relative to private banks: lower marginal costs from enforcement and recovery technologies and from exemption from layers of banking regulation (Section 2.2.1 and Appendix C.4.3), and lower markups consistent with its dual objective of profitability and export promotion, mirroring government-owned banks in other development contexts (e.g., Fonseca and Matray, 2024; Assuncao, Mityakov and Townsend, 2022).

7.2 EXIM as an Industrial Policy Tool

Industrial policy is often motivated by social wedges that drive private investment away from the social optimum: external economies of scale, learning spillovers, environmental externalities, or geopolitical objectives. Our analysis isolates the specific and observable wedge of financing frictions in export markets. The model shows that relaxing these frictions improves capital allocation as long as policy exposure is not tilted away from constrained firms, a condition summarized by the covariance ρ between policy exposure and firm financing wedges in Lemma 2.

Export credit complements these broader objectives when social and financing wedges align. If the firms, sectors, or destinations that carry large social benefits also face binding export-financing constraints, a transaction-level credit policy addresses both at once; export credit for green-energy producers or strategically important supply chains, for instance, may relax financing constraints while supporting activities with broader social value. The same instrument fails when it is mistargeted: credit to firms whose constraints are slack is inframarginal and has no real effect (Lemma 1), credit tilted toward firms with low financing wedges raises misallocation (the $\rho < 0$ case of Lemma 2), and credit tilted toward firms with low social value moves the economy away from the social optimum.

A policy that relaxes export-financing constraints does not require the government to know more than the private sector about firms’ risks or productivity. Because more constrained firms respond more to a given relaxation, even a uniform program that does not condition on any firm-level

information improves allocative efficiency; allocation worsens only if support is tilted toward unconstrained firms by enough to outweigh this stronger response by the constrained. ECAs therefore need not identify winners: by relaxing an observable financing constraint on specific transactions, they improve allocation without forecasting which sectors will ultimately succeed.

8 Conclusion

Can governments boost exports by providing targeted trade financing? This paper’s findings, based on the natural experiment of the US EXIM Bank’s temporary shutdown, indicate the answer is yes. When EXIM’s sudden closure cut off financing to previously supported exporters, those firms experienced slower revenue growth and reduced capital investment and employment. These effects were especially pronounced for financially constrained firms and for exports to riskier, less financially developed markets, consistent with EXIM financing alleviating credit constraints. Overall, US industries more reliant on EXIM experienced weaker export growth than less-dependent industries.

Taken together, these effects are inconsistent with the view that EXIM primarily transfers taxpayer funds to unconstrained firms that reap windfall profits without expanding production. On the contrary, the contraction of EXIM-dependent firms was more pronounced among those with higher marginal returns to capital, indicating that EXIM financing improves rather than worsens the allocation of resources in the economy, and is an effective tool of industrial policy.

That said, caution is warranted in generalizing our results. First, we estimate the effects of EXIM within its current operational scale. Our results do not address the optimal size of ECAs or imply effectiveness at significantly larger scales. We argue that EXIM’s impact stems from alleviating financing constraints in the private market. Other interventions targeting similar firms, or large-scale expansions of ECA funding, could have lower marginal effectiveness and even exacerbate capital misallocation. Second, as discussed in Section 2.2.1, EXIM operates under specific governance constraints that may be central to its effectiveness. Because this governance varies substantially across countries, generalizing our findings to other ECAs should be done with caution.

Third, because trade relationships involve substantial sunk costs and exhibit considerable stickiness (e.g., [Eaton, Kortum and Kramarz, 2011](#)), our estimates likely underestimate the full long-run impact of EXIM. Existing buyer-seller matches may survive for some time even after financing support is withdrawn, and the gradual growth of the estimated effects over the post-period is consistent with the progressive erosion of established trade relationships. With these forces in mind, our estimates would be a lower bound on the long-run effects of ECA support.

ONLINE APPENDIX FOR
“EXIM’S EXIT: INDUSTRIAL POLICY, EXPORT CREDIT AGENCIES,
AND CAPITAL ALLOCATION”

Adrien Matray Karsten Müller Chenzi Xu Poorya Kabir

June 2026

Table of Contents

A Additional Tables	A.2
B Additional Figures	A.7
C Additional Details on Data and Institutional Context	A.9
C.1 Matching between EXIM, Compustat, and Datamyne	A.9
C.2 Data cleaning	A.9
C.3 Variable Definitions	A.10
C.4 EXIM	A.10
C.5 EXIM Activity During the Curtailment	A.12
D Additional Results	A.13
D.1 Derivation of Foreign to Domestic Sales Pass-Through	A.13
D.2 EXIM share intensity	A.14
D.3 Translating Misallocation Results into Aggregate TFP Losses	A.14
D.4 Industry Misallocation: Alternative Measures of Capital Cost Wedge	A.16
D.5 Firm Financing Frictions: Full Results	A.18
D.6 Destination Market Frictions: Full Results	A.20
D.7 Welfare Accounting: Full Results	A.21
E Model of Export Financing: Equilibrium System and Proofs	A.24
E.1 Notation and Full Equilibrium System	A.24
E.2 CES Demand, Revenue, and Export-Revenue Decomposition	A.25
E.3 Firm Problem and Proofs	A.26
E.4 Welfare and Capital-Market Crowd-Out	A.29

A Additional Tables

Table A.1: EXIM Effect Across Product Aggregation Levels

<i>Product aggregation level</i>	HS-2 (1)	HS-3 (2)	HS-4 (3)	HS-5 (4)	HS-6 (5)
EXIM Exposure $\times$ Post	-5.79** (2.70) [0.034]	-5.28** (2.24) [0.020]	-4.49*** (1.60) [0.005]	-4.74*** (1.75) [0.007]	-4.20** (1.73) [0.015]
<i>Fixed Effects</i>					
Exporter $\times$ Year	✓	✓	✓	✓	✓
Product $\times$ Year	✓	✓	✓	✓	✓
Observations	1,150,362	1,978,251	8,541,850	18,961,838	24,143,761

Notes: The dependent variable is the midpoint growth rate of total exports. The treatment variable is the continuous EXIM exposure measure at the HS-4 level. Fixed effects are exporter $\times$ year and product $\times$ year, where the product classification matches the column header (HS-2 through HS-6). All regressions use midpoint trade weights and cluster standard errors at the HS-4 level. Standard errors in parentheses, p-values in brackets.

Table A.2: Impact on US Product Exports: Robustness to Alternative Control Group

<i>Dependent variable</i>	Exports					
<i>Level of aggregation</i>	HS-4	HS-6	HS-6 $\times$ Destination	HS-6 $\times$ Destination		
	(1)	(2)	(3)	(4)	(5)	(6)
EXIM _{p,o} $\times$ Post _t	-4.57*** (1.52) [0.0028]	-4.57*** (1.52) [0.0027]	-4.57*** (1.52) [0.0027]	-4.55*** (1.45) [0.0017]	-4.22** (1.81) [0.020]	
EXIM _{p,o} $\geq 0.45\%$ $\times$ Post _t						-0.056*** (0.016) [0.00058]
<i>Fixed Effects</i>						
Origin $\times$ Year	✓	✓	✓	✓	✓	✓
Product (HS-4) $\times$ Year	✓	✓	✓	—	—	—
Product (HS-6) $\times$ Year	—	—	—	✓	—	—
Product (HS-6) $\times$ Destination $\times$ Year	—	—	—	—	✓	✓
Observations	174,795	13,909,467	39,610,152	39,610,152	39,610,152	39,610,152

Notes: This table reports estimates on the effect of EXIM's shutdown on total export at the product-by-destination level taken from BACI. The dependent variable is the exports growth rate of origin country o (exporter) to destination country d (importer) of product p at time t relative to 2014 (the year prior to the shock), and is defined as $\Delta Y_{p,o,d,t} = (Y_{p,o,d,t} - Y_{p,o,d,2014}) / [(Y_{p,o,d,t} + Y_{p,o,d,2014}) \times 0.5]$. The sample includes a control group of other exporter countries o with similar export patterns as the US. The control group is defined as the fifteen OECD countries with the highest overlap with the US in their vector of export market shares across products and destinations. EXIM intensity (EXIM_{po}) in columns 1-5 is defined as the total amount of EXIM (in \$) over total exports (in \$) over the period 2007–2010. In column 6, EXIM_{po} $\geq 0.45\%$ is an indicator variable for a product being in the top quartile of treatment value. In columns 1–3, the coefficients and standard errors are identical by construction of the midpoint growth estimator [Beaumont, Matray, Tu and Xu \(2026\)](#). Standard errors are clustered at the HS-4 level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Table A.3: Impact on US Product Exports: Robustness to Alternative Weighting

Dependent variable Weighting	Exports			
	EW	VW: 1%	VW, invariant: 5%	VW, invariant: 1%
	(1)	(2)	(3)	(4)
EXIM _{p,o} × Post _t	-3.72** (1.89) [0.049]	-5.77** (2.57) [0.025]	-5.36** (2.32) [0.021]	-5.24** (2.41) [0.030]
<i>Fixed Effects</i>				
Origin × Year	✓	✓	✓	✓
Product (HS-6) × Destination × Year	✓	✓	✓	✓
Observations	24,143,761	24,143,761	24,143,660	24,143,660

Notes: This table reports estimates on the effect of EXIM's shutdown on total export at the product-by-destination level taken from BACI. The dependent variable is the exports growth rate of origin country o (exporter) to destination country d (importer) of product p at time t relative to 2014 (the year prior to the shock), and is defined as $\Delta Y_{p,o,d,t} = (Y_{p,o,d,t} - Y_{p,o,d,2014}) / [(Y_{p,o,d,t} + Y_{p,o,d,2014}) \times 0.5]$. The sample includes a control group of other exporter countries o with similar export patterns as the US. EXIM intensity is defined as the total amount of EXIM (in \$) over total exports (in \$) over the period 2007–2010. In column 1, the regression is equally weighted at the product (HS-6)-exporter-year level. In column 2, regression weights are winsorized at 1%. In columns 3 and 4, we use time-invariant weights based on the average exports value at the product (HS-6)-exporter-year level over the pre-shutdown period. Standard errors are clustered at the HS-4 level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Table A.4: Impact on Firm Maritime Exports

Dependent variable Sample	Maritime Exports				
	All firms				Listed firms
	(1)	(2)	(3)	(4)	(5)
EXIM _i × Post _t	-0.14*** (0.020) [2.3e-12]	-0.12*** (0.018) [2.0e-11]	-0.15*** (0.020) [9.1e-14]	-0.12*** (0.017) [3.7e-12]	-0.31*** (0.031) [4.0e-22]
<i>Fixed Effects</i>					
Post	✓	—	—	—	—
Product × Post	—	✓	—	—	—
Destination × Post	—	—	✓	—	—
Product × Destination × Post	—	—	—	✓	✓
Observations	1,789,006	1,789,006	1,789,006	1,789,006	142,087

Notes: This table reports the estimated effects of EXIM's shutdown on firms' maritime exports using firm-by-product-by-destination data from bills of lading data collected by Datamyne. Data are collapsed as an average pre (up to 2014) and post period (2015–2019). The dependent variable is calculated as a midpoint growth rate based on the [Beaumont, Matray, Tu and Xu \(2026\)](#) estimator, and defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,t \leq 2014}) / [(Y_{i,t} + Y_{i,t \leq 2014}) \times 0.5]$. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Product fixed effects are at the HS-4 level, and destination fixed effects are at the country level. Standard errors are clustered at the HS-4 level, and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Table A.5: Impact on Firm Revenues: Robustness to Different Industry Definitions

<i>Dependent variable</i>	Total revenues			
	(1)	(2)	(3)	(4)
$EXIM_i \times Post_t$	-0.13*** (0.033) [0.000038]	-0.12*** (0.035) [0.00072]	-0.10*** (0.032) [0.0017]	-0.13*** (0.044) [0.0031]
<i>Fixed Effects</i>				
Exporter $\times$ Year	✓	✓	✓	✓
Industry (1-digit) $\times$ Year	✓	—	—	—
Industry (2-digit) $\times$ Year	—	✓	—	—
Industry (3-digit) $\times$ Year	—	—	✓	—
Industry (4-digit) $\times$ Year	—	—	—	✓
Observations	25,174	25,174	25,174	25,174

Notes: This table reports the estimated effects of EXIM's shutdown on firms' total revenue growth. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, exports Datamyne, or taxable foreign income before 2014. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Table A.6: Impact on Firm Revenues by Separate EXIM Programs

<i>Dependent variable</i>	Total revenues

Notes: This table reports the estimated effects of EXIM's shutdown on firms' total revenue growth. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $EXIM \text{ (working cap)}_i$ is an indicator variable that takes the value one if the firm received EXIM financing under EXIM's lending program. $EXIM \text{ (insurance)}_i$ is an indicator variable that takes the value one if the firm received EXIM financing under EXIM's insurance program. Regressions are unweighted in columns 1 and 2, and they are value weighted by firm exports in columns 3 and 4. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, exports Datamyne, or taxable foreign income before 2014. Industries are SIC-4. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Table A.7: Impact on Employment, Capital, and Profit Rates: Robustness to LHS Winsorization

Observations	11,035	10,863	9,545	9,545

Notes: This table reports cross-sectional regressions of firms' average pre-period (2010–2014) MRPK on EXIM_{*i*}, an indicator equal to one if the firm received EXIM trade financing over the pre-shutdown period, across increasing fixed-effect saturations. MRPK is average revenues over physical capital. Standard errors clustered at the firm level are reported in parentheses and *p*-values in brackets. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

B Additional Figures

Figure B.1: US Export Effects Excluding Products and Destinations Individually

Notes: This figure reports the distribution of β coefficients and t-statistics for the average effect of EXIM's shutdown on aggregate exports at the product-by-destination level in BACI, estimated as in Table 2. Panels (a)–(b) exclude HS-4 products one at a time; panels (c)–(d) exclude destinations one at a time. The dependent variable is the exports growth rate of origin country o (exporter) to destination country d (importer) of product p at time t relative to 2014 (the year prior to the shock), and is defined as $\Delta Y_{p,o,d,t} = (Y_{p,o,d,t} - Y_{p,o,d,2014}) / [(Y_{p,o,d,t} + Y_{p,o,d,2014}) \times 0.5]$. The sample includes a control group of other exporter countries o with similar export patterns as the US. Standard errors are clustered at the HS-4 level.

Figure B.2: Firm-level Effects Excluding Industries Individually: Distribution of β and t-stats

Notes: This figure reports the distribution of β and t-stat for the average effect of EXIM's shutdown on firm revenue, as estimated in Table 3, when we exclude industries (SIC-4) one-by-one. Panel (a) plots the $\hat{\beta}$ reported in Table 3 column 5 in the vertical red dotted line. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014}) / Y_{i,2014}$. Standard errors are clustered by firm.

Figure B.3: Impact of EXIM's Shutdown on Total Revenues: Robustness to Multiple Specifications

Notes: This figure shows the point estimates and 95% confidence intervals when estimating equation (9) and progressively including more stringent sets of fixed effects. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. Standard errors are clustered by firm.

Figure B.4: EXIM's Shutdown and Quarterly Firm Revenues

Notes: This figure plots the point estimate and 95% confidence intervals when estimating equation (9) with quarterly firm total revenues including industry-by-year and exporter-by-year fixed effects. The omitted time period is the second quarter of 2015, corresponding exactly to the quarter of EXIM's shutdown (July, 2015). The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. Standard errors are clustered by firm.

Figure B.5: Impact of EXIM's Shutdown on Other Firm Outcomes

Notes: This figure plots the point estimate and 95% confidence intervals when estimating equation (9) for the following outcomes: total revenues, tangible capital (PP&E), intangible capital (Peters and Taylor, 2017), total capital (tangible + intangible), and employment. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. Standard errors are clustered by firm.

C Additional Details on Data and Institutional Context

C.1 Matching between EXIM, Compustat, and Datamyne

Algorithmic match. All datasets are collapsed at the unique level of firm name, city, and state. Compustat lacks city names but contains zipcodes, from which we recover the city. We harmonize company names by removing punctuation, incorporation status (“Inc,” “LLC,” etc.), and obvious typos, following the STATA command **strclean** (Matray and Xu, 2024).

We match EXIM to Compustat and to Datamyne separately, in three steps using `reclink2` (Wasi and Flaaen, 2015). Steps one and two require exact state and city matches and use a fuzzy name merge iteratively at 99% and then 95% similarity thresholds. Step three drops the state-city requirement to accommodate noisy geographic reporting, imposing a 99% fuzzy name threshold to limit false positives.

Manual verification. We manually inspect all the potential matches that were generated algorithmically in steps one to three. The companies we did not consider a match usually fit into one of the following three categories. The first category is companies with equivalent names but different company endings where it is unclear whether or not a potential match refers to the same company. For example, “Barnett Corp” and “Barnett Inc” could easily be mistaken to refer to the same company, and both are based in the United States. However, the former produces paper products and the latter distributes plumbing and electrical equipment, so we do not treat them as a match. The second category is companies with relatively generic or common names, such as “General Technologies,” of which there are many different firms worldwide. In many of these cases, we cannot know exactly whether a firm is a match or not, so we keep them unmatched. The third category is cases of holding or group companies that may refer to several firms. For example, “Magna Group” could refer to the Canadian car parts manufacturer or to Magna International, the Korean subsidiary of lubricant producer ITW PP & F headquartered in Shanghai, or several other chemical companies called Magna. In these cases, we also do not treat them as matches.

C.2 Data cleaning

Compustat. Starting from the universe of Compustat, we remove financials (`sic = 6`), utilities (`sic = 49`), “foreign government entities” (`sic = 8888`), and “international affairs and non operating establishments” (`sic = 9`); observations with missing fiscal year, fiscal periods shorter than 12 months (`pddur ≠ 12`), foreign incorporation or headquarters (`fic ≠ “USA”` or `loc ≠ “USA”`), and negative or missing revenues (`sale`) or assets (`at`); and rare duplicate `gvkey`-years, keeping the first observation after sorting by `gvkey` and date. We restrict the sample to 2010–2019, drop firms entering after the 2014 shock, require observation in 2014, and winsorize baseline firm-level ratios and growth rates at 5%.

BACI. BACI is already cleaned and harmonized from raw Comtrade data, so we only drop undefined importers (ISO code “NA”) and cells where the US never exports. The latter restriction matches our preferred aggregate-export specification, where destination-by-product (HS6)-by-year

fixed effects ($\gamma_{p,d,t}$) restrict identifying variation to destination-product-year cells with US exports; including all cells yields quantitatively similar results.

EXIM loan database. This database reports the financing instrument (loan, guarantee, etc.), US exporting firm, export-product NAICS code, and support value. We include all instruments and, for exposition, refer to them as “loans.” Observations without export-product information are excluded from the product-level exposure measure ($EXIM_{p,o}$), accounting for 3% of pre-shutdown observations and 13% of loan value. Observations without a specific firm, typically because multiple firms are funded, are excluded from the firm-level exposure measure ($EXIM_i$), accounting for 4% of observations and 16% of value. Overall, 1.6% of observations and 12% of value enter neither measure because both the firm and product are unspecified.

Datamyne Datamyne records individual shipments, including product codes, destinations, and shipment weight, but has three limitations: it covers only seaborne trade, about 35% of US exports (International Trade Administration, 2022); it reports shipment volumes, with imputed export values missing for 18% of shipments; and it is less reliable before 2013, so we use 2013–2019.

C.3 Variable Definitions

Variable	Definition
Exporter	Firm reports positive value of: foreign taxable income ($txfo$ and $pifo$), or maritime export in Datamyne, or EXIM financing, or appears in the Hoberg and Moon (2017) dataset
Asset	at
Capital	$ppent$
Employment	emp
Total sales	$sale$
ROA	$(oibdp - dp)/at$
Leverage	$(dltt + dlc)/ppent_{t-1}$
Lobbying	$sum_lobby_exp/sale$
Financing friction in 10K	$delaycon$ in Hoberg-Maskimovic dataset
Profit margin	$(ib + dp)/sale$
MRPK	$sale/ppent$
Dividend intensity	$dvc/ebitda_{t-1}$
Coverage ratio (industry)	Median at SIC-4 of $dlc/ebitda$

For a comparative overview of export credit agencies’ mandates, operational constraints, and product tools across countries, see [Matray, Mueller, Xu and Shen \(2026\)](#). We focus here on the institutional features of the US EXIM that are most directly relevant to our identification strategy.

C.4 EXIM

C.4.1 US Federal government operational constraints

There are three main federal operational constraints EXIM faces.

First, the WTO Agreement on Subsidies and Countervailing Measures requires EXIM to remain self-financing: premium rates must be adequate to cover long-term operating costs and losses, and

loans must reflect the cost and risk of the underlying programs.¹

Second, the Federal Credit Reform Act of 1990 (Section 9) requires each EXIM transaction to be subsidy-neutral or generate negative subsidy, with costs justified if they exceed revenues or savings.

Third, EXIM is subject to congressional oversight (administered through the Office of Congressional and Intergovernmental Affairs), independent annual audits, and a 2% default-rate cap; breaching the cap triggers an immediate operational freeze by Congress.²

Budget procurement process. EXIM has a structured budget procurement process that begins annually with the submission of the Congressional Budget Justification. This document outlines anticipated costs for the fiscal year, categorized into key areas such as administration, program support, and provisions for defaults and losses. Additionally, it addresses funding for other time-variant needs like cybersecurity, support for Subject Matter Experts (SMEs), and assistance programs targeting Minority and Women-Owned Businesses (MWOBs).

EXIM's primary revenues are fees on Guarantees and Insurance and interest on Loans. There are also additional revenues coming from charges associated with the administration of its credit and insurance products, such as application fees, exposure fees, and other related service charges.

C.4.2 EXIM tools

EXIM supports US exporters through four main products: loan guarantees, insurance against customer credit losses, direct loans, and working capital loans.

The four products differ in coverage and term. Loan guarantees cover up to 100% of principal and interest and can be applied to short- and long-term loans. Export credit insurance covers less than 100% and is designed to encourage US exporters to extend short-term trade credit to overseas customers, with insured foreign receivables eligible as collateral for short-term borrowing. Direct loans are long-term and carry fixed interest rates, suitable for capital-intensive projects. Working capital loans are short-term at fixed or floating rates, designed for exporters' operational needs.

EXIM offers financing across a range of terms: medium-term (up to 7 years, transactions under \$10M), long-term (up to 10 years, extendable to 12 for civil aircraft and non-nuclear power plants and to 18 for nuclear power and renewable-energy projects), and short-term (up to 360 days, primarily through Financial Institution Buyer Credit and Single Buyer Export Credit policies).

Process for obtaining EXIM funding. The underwriting for direct loans and long-term loan guarantees, as well as some medium-term and working capital loans, is performed by EXIM loan officers. For some of its programs, especially medium-term and working capital loan guarantees, EXIM delegates credit decisions and underwriting to a selected group of "delegated authority lenders." To limit the risks and potential conflicts of interest inherent when working with third-party lenders, EXIM imposes underwriting requirements and independently reviews these transactions.

Each EXIM authorization is attached to one export transaction with one primary product, identified by a 4 or 6-digit NAICS/SIC code. In the pre-2014 sample, 1,140 out of 28,396 autho-

¹See Annex I, clause (j) of the Agreement.

²Authority for EXIM comes from the Government Corporation Control Act of 1945 and the Legislative Reorganization Act of 1946. During the Covid pandemic, the default-rate cap was temporarily raised to 4%, but this is outside our sample period.

rizations (4.0% by count, 15.2% by approved dollar amount) bundle multiple products and carry no primary code; we drop these when building $EXIM_{p,o}$, so the industry-level aggregation is free of double counting. A multi-product exporter may receive several authorizations in a year, but each corresponds to a distinct transaction with a distinct product as underlying collateral. We verify this by confirming that the sum of transaction-level authorizations in our micro data matches the aggregate totals reported on EXIM’s website.

After EXIM receives an application, it is screened for completeness and minimum eligibility requirements. To qualify for these programs, the goods and services must be U.S.-origin and shipped from the United States to a foreign buyer. In addition, businesses that submit applications must have operated for at least three years, employ at least one full-time individual, and maintain a positive net worth. Next, applications are evaluated in terms of their compliance with EXIM’s policies on credit risk, and financing terms and collateral requirements are determined. Finally, the loan officer makes a decision to approve or deny an application.

C.4.3 Institutional Advantages

As a US government agency, EXIM has access to risk-assessment and loss-recovery capabilities that the private sector does not. These institutional advantages are not required for the welfare argument developed in our model (a uniform expansion of pledgeability raises export capital regardless of whether the lender has superior information or enforcement technologies), but they help to explain why EXIM operates in markets where private financiers do not.

Information and risk assessment. EXIM benefits from access to government information networks unavailable to private lenders: it consults statutorily with the Departments of State and Treasury on transactions involving significant country risk and exchanges information with 19 federal agencies through the Trade Promotion Coordinating Committee.³

Enforcement and recovery. As a US government agency, EXIM has loss-recovery capabilities private lenders lack. Defaulting on an EXIM loan is equivalent to defaulting on the US government itself: EXIM can convert commercial claims into sovereign obligations, participate in Paris Club restructuring negotiations, and pursue claims in international courts with authority to seize debtor assets in foreign jurisdictions.

C.5 EXIM Activity During the Curtailment

Figure 1 shows the total amount of EXIM authorizations by year. During the curtailment period (2015–2019), EXIM activity dropped dramatically but did not fall to zero. The composition of residual activity changed substantially. During the pre-curtailment period (2010–2014), guarantees accounted for \$64.3 billion across 1,048 authorizations, working-capital programs for \$13.7 billion across 2,886 authorizations, and direct loans for \$28.6 billion across 258 authorizations. During the curtailment, these fell to \$6.8 billion (362 authorizations), \$4.2 billion (1,110 authorizations),

³Since its 2019 reauthorization, EXIM has also increased its coordination with national security agencies on transactions with geopolitical implications. EXIM can also draw on country-specific assessments from US embassies, where Foreign Commercial Service officers monitor local business conditions and contract enforcement.

and \$5.1 billion across only 12 authorizations, respectively. By contrast, export credit insurance (which consists of small-ticket items below the \$10 million board-approval threshold) continued at a reduced pace (\$13.4 billion across 11,271 authorizations during the curtailment, compared to \$27.9 billion across 15,699 authorizations in the pre-curtailment period). This shows that residual EXIM activity shifted toward insurance and working-capital programs, while direct loans and guarantees contracted sharply.

C.5.1 EXIM Expense

We collect all of the Annual Reports published by EXIM from 2006 to 2023 where we focus on the bank’s “Balance sheet” and its “Statement of net costs” in each publication.

Interest expense paid to the US Treasury. We calculate EXIM’s annual interest expense by combining information from the balance sheets and statement of net costs. The balance sheets provide the budget allocation from the US Treasury (named “intergovernmental debt”), which is the amount on which EXIM pays interest expense each year. The statement of net costs provides a line item for the interest expense on the loan program. We calculate the interest rate by dividing the interest expense by the stock of intergovernmental debt.

Figure C.1 plots EXIM’s interest expense rate along with the 30-year US Treasury bond. We include all of the years for which these data exist in full. On average, EXIM’s interest rate expense is 60 basis points higher than the 30 year rate (4.3% versus 3.7%). In the pre-shutdown period (2006 to 2014 inclusive), EXIM’s rate is 80 basis points higher (4.8% versus 4.0%).

Figure C.1: EXIM’s Annual Interest Expense

Notes: This figure plots the time series of EXIM’s interest expense from the authors’ calculations. The data stop in 2017 because EXIM’s annual statement of net costs were no longer sufficiently disaggregated to conduct this calculation.

D Additional Results

D.1 Derivation of Foreign to Domestic Sales Pass-Through

To calculate the pass-through from export to domestic sales, we compute the ratio of sales elasticities: $\frac{\epsilon_{Exports}^{Domestic}}{\epsilon_{Exports}} = \frac{\Delta Domestic}{\Delta Exports} \times \frac{Exports}{Domestic}$, where Δ denotes the dollar change in sales in re-

sponse to EXIM and “*Exports*” and “*Domestic*” denote initial sales. Using $\Delta TotalRevenues = \Delta Exports + \Delta Domestic$, $\frac{\partial Total revenues}{\partial EXIM} = 4.9$, and $\frac{\partial Exports}{\partial EXIM} = 4.49$, we obtain $\frac{\partial Dom}{\partial EXIM} = 0.51$. Thus, $\frac{\partial Dom}{\partial EXIM} \times \frac{\partial EXIM}{\partial Exports} = \frac{\partial Dom}{\partial Exports} \approx \frac{\Delta Dom}{\Delta Exports} = \frac{0.51}{4.49}$.

To calculate $\frac{Exports}{Domestic}$, we follow [Bernard, Jensen, Redding and Schott \(2018\)](#), which finds that exports account for approximately 20% of sales among firms with positive exports. Because Compustat firms are larger and exporting is concentrated among larger firms, we use the Compustat segment-data foreign-revenue share of 40% as an upper bound.

Taking these two values as bounds, we calculate that $\frac{Exports}{Domestic} \in [0.25 - 0.66]$.⁴ Together, these magnitudes imply a pass-through of foreign to domestic sales of 2.8% to 7.5%.

D.2 EXIM share intensity

Our baseline firm-level specification treats EXIM exposure as binary: a firm is treated if it received any EXIM financing prior to the shutdown. In this section, we explore whether the effects vary with the intensity of EXIM support. We construct two continuous measures of treatment intensity for each treated firm: (i) average annual EXIM financing divided by average annual total revenue, and (ii) average annual EXIM financing divided by average annual foreign sales, both computed over 2007–2014. We then split treated firms into “Low” and “High” intensity groups based on the within-SIC-4 industry median of each measure. Each regression compares treated firms in a given intensity group against all untreated firms, so that the control group remains identical across columns. [Table D.1](#) reports the results for revenue growth and tangible capital growth.

D.3 Translating Misallocation Results into Aggregate TFP Losses

To quantify the aggregate productivity consequences of the EXIM shutdown, we adapt the Solow residual decomposition of [Bau and Matray \(2023\)](#). The key equation expresses the change in the Solow residual as a sum of firm-level contributions:

$$\Delta Solow = \sum_i \lambda_i \sum_{x \in \{K, L\}} \alpha_i^x \frac{\tau_i^x}{1 + \tau_i^x} \Delta \log x_i, \quad (D.1)$$

where λ_i is firm i ’s revenue share within its industry, α_i^x is the output elasticity with respect to factor x , τ_i^x is the pre-shock input wedge, and $\Delta \log x_i$ is the change in factor usage caused by the policy.

We implement this formula as follows. We split treated firms into high- and low-MRPK groups (above/below the within-SIC-4 median) and estimate the effect of the EXIM shutdown on capital and labor growth separately for each group, using our baseline difference-in-differences specification. The estimated coefficients yield the predicted $\Delta \log K_i$ and $\Delta \log L_i$ for each treated firm (untreated firms contribute zero). We construct capital wedges as $\tau_i^K = \alpha_K \cdot MRPK_i / r - 1$ and labor wedges analogously, using pre-period values and setting $r = 10\%$ following [Hsieh and Klenow \(2009a\)](#). The

⁴If exports is 25% of total revenue, domestic sales is $100\% - 20\% = 80\%$, hence $\frac{Exports}{Domestic} = \frac{0.20}{0.80} = 0.25$. If instead, exports is 40% of total revenue, we have that $\frac{Exports}{Domestic} = \frac{0.40}{(1-0.40)} = 0.66$.

Table D.1: Impact on Revenue and Capital by EXIM Intensity (Within SIC-4)

EXIM Intensity	Revenue				Capital

Observations	24,850	24,179	24,835	24,194	24,317	23,643	24,296	23,664

Notes: This table reports the estimated effects of EXIM’s shutdown on firm revenue growth (columns 1–4) and tangible capital growth (columns 5–8), split by EXIM intensity. Intensity is measured among treated firms and split at the within-SIC-4 industry median. “Low” includes treated firms below the within-industry median plus all untreated firms; “High” includes treated firms above the within-industry median plus all untreated firms. EXIM/Revenue and EXIM/Foreign sales are computed as average annual EXIM financing divided by average annual revenue (or foreign sales) over 2007–2014. The dependent variables are growth rates relative to 2014 (winsorized at the 5th and 95th percentiles). All specifications include exporter × year and industry × year fixed effects and are weighted by firm sales (winsorized at the 5th percentile). Standard errors are clustered at the firm level. Significance levels: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

wedge weight $\tau_i^x / (1 + \tau_i^x)$ captures how distorted the firm is: firms facing no distortion contribute nothing to the Solow residual even if their inputs change.

We consider two versions. In a one-factor model ($\alpha_K = 1$), only capital reallocation matters, and the estimated TFP loss from the EXIM shutdown is -1.56 percentage points (SE = 0.55). In a two-factor model ($\alpha_K = 1/3$, $\alpha_L = 2/3$), both capital and labor channels contribute, yielding a total TFP loss of -1.22 percentage points (SE = 0.37), of which -0.47 pp comes from capital misallocation and -0.76 pp from labor misallocation.

These estimates assign the same predicted factor change to all treated firms within each MRPK group. In practice, however, treated firms differ substantially in their reliance on EXIM financing. To account for this heterogeneity, we rescale each firm’s predicted effect in proportion to its pre-shock EXIM intensity (EXIM amount divided by foreign sales), normalized by the group mean so that the average treated firm still receives the regression-estimated effect. The logic is analogous to a shift-share design: the binary DiD identifies the average per-unit effect, while the aggregation applies firm-specific “shares” reflecting actual EXIM reliance. Under this approach, the estimated TFP loss is -0.56 percentage points in the one-factor model (SE = 0.19) and -0.43 percentage points in the two-factor model (SE = 0.12). The intensity-weighted estimates are smaller because large firms, which dominate the aggregate through their revenue weights, tend to have low EXIM reliance relative to their size. Taken together, our estimates suggest that the EXIM shutdown reduced aggregate TFP by -0.43 to -1.56 percentage points.

D.4 Industry Misallocation: Alternative Measures of Capital Cost Wedge

This section discusses alternative ways of measuring the dispersion in firm capital input cost wedge and reports the results in [Table D.2](#). In columns 1–2, we directly estimate firms’ production function using the control approach of [Olley and Pakes \(1996\)](#), and compute firm MRPK. In columns 3–4, we follow [Baqee and Farhi \(2020a\)](#) and adopt the user cost approach that is also used in [Gutierrez and Philippon \(2016\)](#), as well as [Foster, Haltiwanger and Syverson \(2008\)](#). This technique computes the user-cost of capital following [Hall and Jorgenson \(1967\)](#), where the rental price incorporates the risk-free rate, industry-specific depreciation, and industry-level risk premia. The Appendix of [Baqee and Farhi \(2020a\)](#) provides a detailed explanation of the computation. In columns 5–6, we extend our analysis to examine the dispersion in TFPR, estimated using the technique of [Olley and Pakes \(1996\)](#). Following [Hsieh and Klenow \(2009b\)](#), this dispersion reflects the dispersion in cost wedges for all inputs that the firm uses.

When firms have a more general CES production function (where Cobb-Douglas represents the special case when the elasticity of substitution across inputs equals one), it is no longer possible to estimate the capital input cost wedge specifically. However, one can still estimate the capital cost wedge relative to other inputs used by the firm, as highlighted in [Whited and Zhao \(2021\)](#). To formalize this intuition, assume that firms have a standard CES production function where a firm i in section s generates total revenue Y by using capital and labor:

$$Y_{si} = A_{si} \left(\alpha_s K_{si}^{\frac{\gamma-1}{\gamma}} + (1 - \alpha_s) L_{si}^{\frac{\gamma-1}{\gamma}} \right)^{\frac{\gamma}{\gamma-1}}, \quad (\text{D.2})$$

where α_s is the relative weight of capital in production, γ is the elasticity of substitution between capital and labor, and A_{si} is the firm’s technological efficiency parameter. In the non-distorted economy, firms pay their capital r and labor w , but as is standard in the misallocation literature, each input can have an extra wedge. The firm’s nominal profit π_{si} is given by:

$$\pi_{si} = Y_{si} - [(1 + \tau^K_{si})rK_{si} + (1 + \tau^L_{si})wL_{si}], \quad (\text{D.3})$$

where τ^X_{si} represents the additional wedge on input X (either capital or labor) that determines the marginal return required for investing in that input.

The firm’s profit maximization problem can be solved in two steps. First, the firm minimizes its cost by choosing K and L subject to achieving a fixed output level $\bar{Y}_{si}$ in equation [\(D.2\)](#). This optimization yields the following solution for the optimal ratio of capital to labor:

$$\frac{K_{si}}{L_{si}} = \left(\frac{\alpha_s}{1 - \alpha_s} \times \frac{(1 + \tau^L_{si})w}{(1 + \tau^K_{si})r} \right)^{\gamma}. \quad (\text{D.4})$$

As long as α_s and γ do not vary within firms in a sector or sector-by-size bin, firms in the same cell should have similar input ratios, and dispersion within a cell will reflect differences in the value of the ratio of input cost wedges. Thus, while we can no longer measure the capital cost wedge directly (which is possible under Cobb-Douglas production), we can still measure it relative to the

value of the wedge on the other input. In this framework, the labor to capital ratio reveals the relative capital cost wedge.

We implement this approach empirically in columns 7–10. We use two alternative measures to capture the relative input wedges: the ratio of COGS (Cost of Goods Sold) over capital (columns 7–8) and the ratio of labor over capital (columns 9–10). COGS provides an alternative measure of variable input costs that may be less subject to measurement error than reported labor costs in some contexts.

In all the different ways of estimating the ex-ante wedge distortions that firms face, we find that EXIM’s shutdown leads to larger contractions for firms that are ex-ante more constrained, confirming that EXIM’s shutdown increased capital misallocation.

Table D.2: Impact on Capital Misallocation: Alternative Measures of MRPK

Dependent variable Measure of wedge distortion Sample	Investment									
	MRPK Olley-Pakes		MRPK User Cost		TFPR: Olley Pakes		CES: Capital / COGS markup		CES: Capital / L markup	
	Low	High	Low	High	Low	High	Low	High	Low	High

Industry × Size quartile × Year	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Observations	13,420	7,764	14,983	9,010	13,446	7,738	14,420	8,570	14,960	9,050

Notes: This table reports the estimated effects of EXIM’s shutdown on firms’ capital investment. Depending on whether a firm is high or low MRPK. We measure MRPK by estimating the firm production function following Olley-Pakes (1996) in columns 1–2. In columns 3–4, we follow [Baqaee and Farhi \(2020a\)](#) and adopt the user cost approach. In columns 5–6, we report compute firm total TFPR. Finally in columns 7–10, we use the ratio of COGS over capital (columns 7–8) and total employment over capital (columns 9–10), which when the firm has a CES production function, will reflect the capital input cost wedge relative to the other input cost wedge. In all columns, we compute the value in the pre-shock period, average at the firm level, and sort firms along the median of their SIC-4 × quartile of asset distribution. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. *Post_t* is an indicator variable equal to 1 for the years 2015 to 2019. *EXIM_i* is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, international activity in their 10-Ks, exports in Datamyne, or taxable foreign income before 2014. Industries are SIC-2. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and *p*-values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Sorting MRPK within destination cells. The cells in the main analysis (SIC-4 × size × risk) hold fixed industry-, size-, and risk-related sources of MRPK dispersion. As a further check, [Table D.3](#) sorts firms into high- and low-MRPK groups within SIC-4 × size × destination cells, where a firm’s destination is its modal pre-period destination from Datamyne bill-of-lading data; this absorbs destination-market sources of MRPK dispersion such as destination-specific risk or returns. The differential contraction of high-MRPK firms is similar to the baseline, whether destination is defined by the buyer’s (“business”) country (columns 1–3) or the goods’ (“output”) country (columns 4–6).

Table D.3: Impact on Capital Misallocation: Sorting MRPK Within Destination Cells

Notes: This table re-estimates the misallocation triple-difference of Table 5 sorting firms into high- and low-MRPK groups within SIC-4 × size × destination cells. A firm’s destination is its modal pre-period destination, measured from Datamyne bill-of-lading data; columns 1–3 define it by the buyer’s (“business”) country and columns 4–6 by the goods’ (“output”) country. The dependent variable is the growth rate of capital relative to 2014. Standard errors clustered at the firm level are reported in parentheses and *p*-values in brackets. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels.

D.5 Firm Financing Frictions: Full Results

This section reports the full results referenced in Section 6.3.1 on whether the EXIM shutdown’s effect on investment is concentrated among firms identified ex ante as more financially constrained.

Specification. We use four standard proxies to capture financial constraints. For each, we sort firms into terciles and define an indicator variable, *Constrained*, equal to one for the tercile that the literature associates with tighter financing. We estimate heterogeneous effects of EXIM’s shutdown using triple-difference regressions that interact *EXIM* × *Post* with each constraint proxy:

$$\begin{aligned} \Delta Y_{i,j,t} = & \beta_1 EXIM_{i,j} \times Post_t \times I_i^{Constrained} + \beta_2 EXIM_{i,j} \times \delta_t \\ & + I_i^{Constrained} \otimes \left[\gamma_{j,t} + Exporter_{i,t_0} \times \delta_t + X_{i,t_0} \times \delta_t + \varepsilon_{i,j,t} \right] \end{aligned} \quad (D.5)$$

$\Delta Y_{i,j,t}$ denotes the growth rate of an outcome between t and 2014, $I_i^{Constrained}$ is an indicator variable that takes the value one if firm i is constrained in the pre-period, and $\otimes$ is the outer product so that we include all possible combinations of the different terms, including *EXIM* × *Year*, which absorbs systematic differences between treated and control units. Standard errors are clustered at the firm level.

Proxies. Column 2 of Table D.4 sorts on firm age, measured as years since the firm’s first appearance in Compustat as of 2014; the indicator equals one for firms in the bottom tercile of age, since young firms typically lack the reputation and banking relationships that mature firms accu-

mulate (e.g., [Hadlock and Pierce, 2010](#)). Column 3 sorts on industry leverage (e.g., [Giroud and Mueller, 2017](#); [Friedrich and Zator, 2023](#)), measured as the SIC4 median of total debt over total tangible-plus-intangible capital. Column 4 sorts on the [Hoberg and Maksimovic \(2015\)](#) private-debt delay measure, computed firm by firm from the textual analysis of each firm’s 10-K filing in its first pre-period year. Column 5 sorts on the industry coverage ratio (SIC4 median of short-term debt over cash flow), motivated by the fact that EXIM’s trade financing is a source of short-term working capital. In columns 3 and 5, the SIC4-median aggregation isolates industry-level variation in financing-friction exposure and absorbs idiosyncratic firm-level noise.

Within the group of EXIM-dependent firms, those that are most constrained experience larger investment cuts. This heterogeneity indicates that export financing is particularly important for firms with limited alternative funding sources, highlighting EXIM’s role as a complement to private-sector financing.

Table D.4: Role of Financing Frictions

<i>Dependent variable</i> <i>Financing frictions proxy:</i>	Investment				
		Age	Leverage	Hoberg and Maskimovic (2015)	Coverage ratio
	(1)	(2)	(3)	(4)	(5)
$EXIM_i \times Post_t$	-0.14*** (0.044) [0.0014]				
$EXIM_i \times Post_t \times I_i^{Constrained}$		-0.29** (0.12) [0.015]	-0.36*** (0.12) [0.0022]	-0.19** (0.086) [0.027]	-0.24*** (0.083) [0.0043]
<i>Fixed Effects</i>

Exporter×Year	—	✓	✓	✓	✓
Industry×Year	—	✓	✓	✓	✓
EXIM×Year	—	✓	✓	✓	✓
Observations	24,635	24,635	20,662	24,630	24,606

Notes: This table reports the estimated effects of EXIM’s shutdown on firms’ investment. The dependent variable is the growth rate relative to 2014 defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,2014})/Y_{i,2014}$. $I_i^{Constrained}$ is an indicator that equals one when the firm or its industry is in the constrained tercile of the proxy. Column 2 uses firm age, with the indicator equal to one for firms in the *bottom* tercile of age in 2014, where age is the number of years since the firm’s first appearance in Compustat. Column 3 uses the SIC4 median of pre-period total debt over total (tangible plus intangible) capital. Column 4 uses the firm-level [Hoberg and Maksimovic \(2015\)](#) private-debt delay constraint, evaluated at the firm’s first pre-period observation. Column 5 uses the SIC4 median of pre-period short-term debt over cash flow. For columns 3 to 5, the indicator equals one for firms in the *top* tercile of the proxy. Tercile splits are revenue-weighted (pre-period winsorized revenue) and unconditional. $Post_t$ is an indicator variable equal to 1 for the years 2015 to 2019. $EXIM_i$ is an indicator variable that equals 1 if the firm received trade financing from EXIM over the pre-shutdown period. Exporter fixed effect is an indicator variable that equals 1 if the firm reports positive EXIM financing, foreign sales in Compustat Segment, international activity in their 10-Ks, exports in Datamyne, or taxable foreign income before 2014. Industries are SIC-2. In columns 2 to 5, Exporter×Year and Industry×Year fixed effects are also interacted with the three-level tercile of the sorting variable, and EXIM×Year fixed effects are included. Standard errors are clustered at the firm level and are reported in the line below the point estimate in parenthesis, and p -values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

Alternative non-financing channels. We considered two alternative mechanisms for the firm-level heterogeneity. First, ECAs sometimes operate alongside broader export-promotion initiatives. Although EXIM is primarily a financing institution rather than an export-promotion agency, its

activities could theoretically facilitate trade relationships and provide market intelligence. However, since EXIM does not provide any “marketing-related programs,” these promotional channels play at most a minor role in explaining our results. Second, private financial institutions may have hesitated to fill the gap in trade financing due to uncertainty about when EXIM would resume operations, leading to a “wait-and-see” approach in the trade finance market. However, given that the shutdown lasted for many years, it is implausible that uncertainty was the primary driver of limited private sector entry. Moreover, EXIM is institutionally designed to operate only in market segments in which private lenders are unable or unwilling to participate, so the lack of entry is unlikely to be explained by fears of future competition with the agency. Finally, it is difficult to reconcile a general aversion to uncertainty with the cross-sectional heterogeneity by firm and destination market that we document.

D.6 Destination Market Frictions: Full Results

This section reports the results referenced in Section 6.3.1 on the role of destination-market frictions.

We use firm-level estimates from Datamyne, which allow us to use variation across firms within a given product-destination market. We focus on the manufacturing subsample (HS2 28–97) and use four proxies that capture distinct dimensions of the banking and institutional environment in the destination country.

The first two proxies measure the depth of international banking presence in the destination. Column 1 uses total US bank claims on the destination country from the FFIEC Country Exposure Report (E.16), which directly captures the extent to which American banks have a financial footprint in the destination market. Countries with no reported US bank claims are assigned zero, representing the highest friction. Column 2 uses the share of state-owned bank assets from the Panizza (2024) Bank Ownership Database. In countries where the banking sector is dominated by state-owned institutions, foreign exporters are less likely to find commercial counterparts willing to provide trade financing, making EXIM’s role more critical.

The third and fourth proxies capture the broader institutional and financial environment. Column 3 uses the rule of law index from the Worldwide Governance Indicators (Kaufmann, Kraay and Mastruzzi, 2010), which measures the quality of contract enforcement and property rights in the destination country. Column 4 uses the ratio of private credit to GDP from the World Bank’s World Development Indicators, a standard measure of financial development.

For each proxy, we sort destination countries into terciles based on pre-period (2010–2014) averages. We estimate a triple-difference specification where we interact the EXIM treatment variable with an indicator for high-friction destinations (top tercile), including $HS-4 \times destination \times period$ fixed effects. Regressions use firm-equal weights, where the within-firm weight is normalized to sum to one per firm, ensuring that each firm receives equal weight regardless of the number of shipments.

Table D.5 reports the results. Across all four proxies, the EXIM shutdown effect is more negative in high-friction destinations. The differential is statistically significant at the 5% level for three of the four proxies, and at the 10% level for private credit to GDP. The magnitudes are economically

meaningful: destinations in the top tercile of friction experience an EXIM shutdown effect that is 30 to 55 percent larger than destinations in the bottom two terciles.

Table D.5: Destination Market Frictions: Banking and Institutional Environment

<i>Dependent variable</i>	Exports (TEUs)			
	US bank presence	State-owned banks	Rule of law	Financial development
<i>Destination friction proxy:</i>	(1)	(2)	(3)	(4)

<i>Fixed Effects</i>				
HS-4 $\times$ Destination $\times$ Post _t	✓	✓	✓	✓
$\text{EXIM}_{f,p,d} \times \text{Post}_t$	✓	✓	✓	✓
Observations	1,058,036	1,050,590	1,050,216	1,020,744

Notes: This table reports triple-difference estimates of EXIM’s shutdown on firm-level exports using Datamyne bill-of-lading data, restricted to manufacturing products (HS2 28–97). Data are collapsed as an average pre (up to 2014) and post period (2015–2019). The dependent variable is calculated as a midpoint growth rate based on the [Beaumont, Matray, Tu and Xu \(2026\)](#) estimator, and defined as $\Delta Y_{i,t} = (Y_{i,t} - Y_{i,t \leq 2014}) / [(Y_{i,t} + Y_{i,t \leq 2014}) \times 0.5]$. EXIM intensity ($\text{EXIM}_{f,p,d}$) is defined at the firm-by-product-by-destination level. $I_d^{\text{Constrained}}$ is an indicator variable that takes the value one if the destination country is in the top tercile of the friction proxy, measured as the pre-period (2010–2014) average. “US bank presence” is total US bank claims on the destination country from the FFIEC Country Exposure Report (E.16); countries with no reported claims are assigned zero. “State-owned banks” is the share of state-owned bank assets from [Panizza \(2024\)](#). “Rule of law” is the indicator from the Worldwide Governance Indicators ([Kaufmann, Kraay and Mastruzzi, 2010](#)). “Financial development” is private credit to GDP from the World Bank. All regressions are weighted by firm-equal weights (within-firm weight normalized to sum to one per firm) and include HS-4 $\times$ destination $\times$ period fixed effects, which absorb $\text{EXIM}_{f,p,d} \times \text{Post}_t$. Standard errors are clustered at the HS-4 level, and are reported in the line below the point estimate in parenthesis, and *p*-values are reported in brackets below them. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

D.7 Welfare Accounting: Full Results

This section reports the full results for the two welfare offsets discussed in [Section 7.1.3](#): terms-of-trade effects and crowding out of domestic producer capital.

D.7.1 Terms-of-Trade Effects

We test for terms-of-trade effects directly using BACI unit values, computed as the ratio of export value to quantity at the HS-6 product-by-destination-by-year level. We apply our baseline difference-in-differences specification using the same synthetic control group of OECD exporters as in the main analysis.

We present two complementary specifications in [Table D.6](#). In columns (1)–(3), the dependent variable is the log level of the unit value, with unit fixed effects (exporter $\times$ product or exporter $\times$ product $\times$ destination) absorbing time-invariant price differences across trade flows. In columns (4)–(6), the dependent variable is the log growth rate of unit values relative to 2014 (trimmed at 5 $\times$ the interquartile range by year to remove outliers driven by compositional changes in quantities). Within each panel we progressively saturate the fixed effects: column (1)/(4) includes

product (HS-4) $\times$ year and origin $\times$ year fixed effects; column (2)/(5) adds product $\times$ destination $\times$ year; and column (3)/(6) uses HS-6 $\times$ destination $\times$ year fixed effects. Standard errors are clustered at the HS-4 level.

Across all six specifications, the coefficient on EXIM exposure is statistically insignificant and switches signs across models, indicating that the EXIM curtailment did not lead to significant changes in the prices of US exports in EXIM-backed products. Since terms-of-trade effects require export prices to move, the absence of a unit-value response implies that terms-of-trade considerations are not first-order in our setting.

Table D.6: Effect of EXIM Curtailment on Unit Values

	Log level			Log growth		
	(1)	(2)	(3)	(4)	(5)	(6)
EXIM _{p,o} $\times$ Post _t	-3.09 (2.18) [0.16]	1.98 (1.22) [0.11]	0.46 (0.99) [0.64]	-2.21 (1.81) [0.22]	2.34 (1.46) [0.11]	0.41 (1.07) [0.70]
<i>Fixed Effects</i>						
Unit	✓	✓	✓	✓	✓	✓
Product (HS-4) $\times$ Year	✓	—	—	✓	—	—
Origin $\times$ Year	✓	✓	✓	✓	✓	✓
Product (HS-4) $\times$ Destination $\times$ Year	—	✓	—	—	✓	—
Product (HS-6) $\times$ Destination $\times$ Year	—	—	✓	—	—	✓
Observations	121,055	8,614,340	23,579,371	105,944	6,456,288	16,737,602

Notes: Unit values are computed as the ratio of export value to quantity from BACI data. In columns (1)–(3), the dependent variable is the log level of the unit value; in columns (4)–(6), it is the log growth rate relative to 2014, trimmed at 5 $\times$ the interquartile range by year. All specifications include unit fixed effects (exporter $\times$ product in columns (1) and (4); exporter $\times$ product $\times$ destination in columns (2)–(3) and (5)–(6)). Column (1)/(4): HS-4 $\times$ year and origin $\times$ year FE. Column (2)/(5): HS-4 $\times$ destination $\times$ year and origin $\times$ year FE. Column (3)/(6): HS-6 $\times$ destination $\times$ year and origin $\times$ year FE. Standard errors in parentheses, *p*-values in brackets, clustered at the HS-4 level.

D.7.2 Domestic Crowding-Out Effects

We test whether EXIM-backed firms expand by drawing inputs away from other US firms, which would impose costs on non-backed firms and cut against the gains for EXIM-financed firms. We define two samples of non-EXIM firms. The first, broader sample includes all non-EXIM-financed firms, which encompasses both EXIM-eligible exporters that did not receive EXIM and pure domestic producers; this gives the largest sample of firms that could absorb input reallocation. The second, stricter sample restricts to firms that sold only domestically in the pre-period. The stricter sample provides the cleanest crowding-out test, since these firms' growth cannot reflect reallocation of export market share and must instead reflect reallocation of inputs from EXIM-backed firms.

For each sample, we assign non-treated firms an exposure measure based on pre-period EXIM intensity in their NAICS-4 industry, defined as EXIM-backed transactions divided by total industry sales. At the state level, this measure is the sales-weighted average of NAICS-4 exposure across manufacturing firms located in the state, with weights computed from pre-period (2010–2014) sales. Both exposure variables are pre-determined and assigned to non-treated firms through their industry or state.

Table D.7 reports the results for the broader non-EXIM sample, and Table D.8 reports the

analogous results for the stricter sample restricted to firms with zero foreign sales in the pre-period. Each table reports industry-level exposure in columns (1)–(3) and state-level exposure in columns (4)–(6), with progressively richer fixed effects. The estimated coefficients are small and statistically insignificant in every cell.

Table D.7: Effect on Non-Treated Firm Revenue

E Model of Export Financing: Equilibrium System and Proofs

E.1 Notation and Full Equilibrium System

Notation. Home and Foreign identify the country of production. A Home firm produces in Home; Foreign producers are located in the RoW. Destination markets are indexed by $m \in \{d, x\}$, with d the Home market and x the export market. For Home firm-level objects, subscripts are ordered firm first and destination market second: $R_{i,m}$, $k_{i,m}$, $z_{i,m}$, and $\mathcal{Z}_{i,m}$. Home aggregates carry only the market subscript, for example $\mathcal{R}_m$ and k_m . Foreign objects carry an F subscript and the relevant destination market, for example $\mathcal{R}_{F,m}$ and $\bar{p}_{F,m}$.

The primitive objects are

$$(\sigma, \{\phi_x, r_x^{adj}, \theta_x, F_x\}, \{a_i, z_{i,d}, z_{i,x}\}_{i=1,2}, D_x, \bar{p}_{F,d}, \bar{p}_{F,x}, K_s(\cdot), T), \quad (\text{E.1})$$

where σ governs substitution, $(\phi_x, r_x^{adj}, \theta_x, F_x)$ govern export finance, $(a_i, z_{i,d}, z_{i,x})$ are firm-level net worth and productivities, D_x is export-market expenditure, $\bar{p}_{F,d}$ and $\bar{p}_{F,x}$ are fixed Foreign prices, $K_s(\cdot)$ is aggregate capital supply, and T is the fiscal cost of the intervention. Aggregate capital supply $K_s(r_k)$ is continuously differentiable with $K'_s(r_k) \geq 0$; the limiting cases of perfectly elastic ($K'_s \rightarrow \infty$) and perfectly inelastic ($K'_s = 0$) supply are recovered as bounds.

The endogenous objects are

$$\{k_{i,d}, k_{i,x}\}_{i=1,2}, \quad \{\lambda_i\}_{i=1,2}, \quad r_k, \quad D_d, \quad (P_d, P_x).$$

For $m \in \{d, x\}$, write

$$R_{i,m}(k_{i,m}; D_m, P_m) \equiv D_m^{1/\sigma} P_m^{(\sigma-1)/\sigma} z_{i,m}^{(\sigma-1)/\sigma} k_{i,m}^{(\sigma-1)/\sigma}.$$

Definition 1 (Equilibrium). *Given primitives (E.1), an equilibrium is a vector*

$$(\{k_{i,d}, k_{i,x}, \lambda_i\}_{i=1,2}, r_k, D_d, P_d, P_x)$$

satisfying the firm optimality conditions (E.2)–(E.3), complementarity (E.4), capital-market clearing (E.5), the Home-income identity (E.6), and the CES price-index consistency conditions (E.7)–(E.8). Existence and local uniqueness in a neighbourhood of the constrained benchmark follow from monotonicity of the CES price-index system and continuity of $K_s(\cdot)$.

The equilibrium conditions are

$$\frac{\partial R_{i,d}(k_{i,d}; D_d, P_d)}{\partial k_{i,d}} = r_k, \quad i = 1, 2, \quad (\text{E.2})$$

$$[1 - \phi_x(r_x^{adj} + \lambda_i)] \frac{\partial R_{i,x}(k_{i,x}; D_x, P_x)}{\partial k_{i,x}} = r_k, \quad i = 1, 2, \quad (\text{E.3})$$

$$0 \leq \lambda_i \perp \theta_x a_i - F_x - \phi_x R_{i,x}(k_{i,x}; D_x, P_x) \geq 0, \quad i = 1, 2, \quad (\text{E.4})$$

$$\sum_{i=1}^2 (k_{i,d} + k_{i,x}) = K_s(r_k), \quad (\text{E.5})$$

$$D_d = I = \mathcal{R}_d + \mathcal{R}_x - T, \quad (\text{E.6})$$

where

$$\mathcal{R}_m \equiv \sum_{i=1}^2 R_{i,m}(k_{i,m}; D_m, P_m), \quad K \equiv \sum_{i=1}^2 (k_{i,d} + k_{i,x}).$$

The CES price indices satisfy

$$P_d = \left[\sum_{i=1}^2 \left(\frac{D_d P_d^{\sigma-1}}{z_{i,d} k_{i,d}} \right)^{(1-\sigma)/\sigma} + \bar{p}_{F,d}^{1-\sigma} \right]^{1/(1-\sigma)}, \quad (\text{E.7})$$

$$P_x = \left[\sum_{i=1}^2 \left(\frac{D_x P_x^{\sigma-1}}{z_{i,x} k_{i,x}} \right)^{(1-\sigma)/\sigma} + \bar{p}_{F,x}^{1-\sigma} \right]^{1/(1-\sigma)}. \quad (\text{E.8})$$

The first two lines are firm optimality conditions. The complementarity condition is the export-financing constraint and its multiplier; $a \perp b$ means $a \geq 0$, $b \geq 0$, and $ab = 0$. The remaining equations close the equilibrium through capital-market clearing, the Home income identity, and CES price-index consistency.

E.2 CES Demand, Revenue, and Export-Revenue Decomposition

Each destination market $m \in \{d, x\}$ has a representative consumer with CES preferences over varieties sourced from Home and Foreign origins:

$$u_m(c_m) = \left(\sum_{o,k} c_{m,o,k}^{(\sigma-1)/\sigma} \right)^{\sigma/(\sigma-1)}, \quad \sigma > 1. \quad (\text{E.9})$$

We model Foreign supply in each destination as a single representative variety with fixed price $\bar{p}_{F,m}$, consistent with the small-Home assumption: Foreign productivity and entry are taken as exogenous, and the CES aggregator nests two Home varieties and one Foreign aggregate.

With constant-returns production $y_i = z_{i,m} k_{i,m}$ and monopolistic competition, firm revenue can be written as

$$R_{i,m} = \mathcal{Z}_{i,m} k_{i,m}^\alpha, \quad \mathcal{Z}_{i,m} = D_m^{1/\sigma} P_m^{(\sigma-1)/\sigma} z_{i,m}^{(\sigma-1)/\sigma}, \quad \alpha = \frac{\sigma-1}{\sigma}.$$

Let

$$\mathcal{R}_x = R_{1,x} + R_{2,x}, \quad k_x = k_{1,x} + k_{2,x}, \quad \Phi_x = \left(\frac{k_{1,x}}{k_x} \right)^\alpha + \left(\frac{k_{2,x}}{k_x} \right)^\alpha,$$

where the expression for Φ_x uses the common export shifter $\mathcal{Z}_{1,x} = \mathcal{Z}_{2,x}$. The Home export share is

$$w_x \equiv \frac{\mathcal{R}_x}{\mathcal{R}_x + \mathcal{R}_{F,x}}.$$

Differentiating $\mathcal{R}_x = \sum_i \mathcal{Z}_{i,x} k_{i,x}^\alpha$, holding firm productivities and trade costs fixed while allowing the export-market price index P_x to adjust, yields

$$d \log \mathcal{R}_x = (1 - w_x) [\alpha d \log k_x + d \log \Phi_x] = (1 - w_x) E_x. \quad (\text{E.10})$$

The allocation-index term can be written as

$$d \log \Phi_x = \alpha (\varpi_{1,x} - s_{1,x}) (d \log k_{1,x} - d \log k_{2,x}), \quad (\text{E.11})$$

where $s_{i,x} \equiv k_{i,x}/k_x$ and $\varpi_{i,x} \equiv R_{i,x}/\mathcal{R}_x$.

E.2.1 Targeting decomposition with N exporters

With N active constrained exporters, the allocation index is $\Phi_x = \sum_{i=1}^N s_{i,x}^\alpha$, and (E.11) generalizes to

$$d \log \Phi_x = \alpha \sum_{i=1}^N (\varpi_{i,x} - s_{i,x}) d \log k_{i,x}, \quad \sum_{i=1}^N \varpi_{i,x} = \sum_{i=1}^N s_{i,x} = 1. \quad (\text{E.12})$$

Lemma 3 (Targeting with N exporters). *Write each firm's realized response as $d \log k_{i,x} = \varepsilon_i d \log \theta_{i,x}$, with cross-firm means $\bar{\varepsilon} \equiv \frac{1}{N} \sum_i \varepsilon_i$ and $\overline{d \log \theta}_x \equiv \frac{1}{N} \sum_i d \log \theta_{i,x}$ and deviations $\tilde{\varepsilon}_i \equiv \varepsilon_i - \bar{\varepsilon}$, $\widetilde{d \log \theta}_{i,x} \equiv d \log \theta_{i,x} - \overline{d \log \theta}_x$. Then*

$$d \log \Phi_x = \alpha \left[\underbrace{\bar{\varepsilon} \sum_i (\varpi_{i,x} - s_{i,x}) d \log \theta_{i,x}}_{\text{policy targeting}} + \underbrace{\overline{d \log \theta}_x \sum_i (\varpi_{i,x} - s_{i,x}) \varepsilon_i}_{\text{per-unit response}} + \underbrace{\sum_i (\varpi_{i,x} - s_{i,x}) \tilde{\varepsilon}_i \widetilde{d \log \theta}_{i,x}}_{\text{interaction}} \right]. \quad (\text{E.13})$$

The policy-targeting term equals $\alpha \bar{\varepsilon} N \text{Cov}_i(\varpi_{i,x} - s_{i,x}, d \log \theta_{i,x})$ and is weakly positive when $\rho \equiv \text{Cov}_i(d \log \theta_{i,x}, \lambda_i) \geq 0$, because $\varpi_{i,x} - s_{i,x}$ is increasing in λ_i under Assumption 1. For $N = 2$ the interaction term is identically zero and (E.13) reduces to the two-term decomposition of Lemma 2 applied to (E.11).

Proof. Since $\sum_i (\varpi_{i,x} - s_{i,x}) = 0$, the constant $\bar{\varepsilon} \overline{d \log \theta}_x$ contributes nothing to (E.12); substituting $d \log k_{i,x} = (\bar{\varepsilon} + \tilde{\varepsilon}_i)(\overline{d \log \theta}_x + \widetilde{d \log \theta}_{i,x})$ and expanding yields the three terms in (E.13). The targeting term equals $N \text{Cov}_i(\varpi_{i,x} - s_{i,x}, d \log \theta_{i,x})$ because $\sum_i (\varpi_{i,x} - s_{i,x}) = 0$. For $N = 2$, $\varpi_{2,x} - s_{2,x} = -(\varpi_{1,x} - s_{1,x})$ and the deviations are equal and opposite, so the interaction term vanishes. $\square$

E.3 Firm Problem and Proofs

E.3.1 Active-exporter choice and MRPK wedge

For an active exporter, the Lagrangian for the export-market choice is

$$\mathcal{L}_i = (1 - r_x^{\text{adj}} \phi_x) R_{i,x}(k_{i,x}) - r_k k_{i,x} - r_x^{\text{adj}} F_x + \lambda_i [\theta_x a_i - F_x - \phi_x R_{i,x}(k_{i,x})].$$

The first-order condition is

$$\frac{\partial \mathcal{L}_i}{\partial k_{i,x}} = (1 - r_x^{\text{adj}} \phi_x) \frac{\partial R_{i,x}}{\partial k_{i,x}} - r_k - \lambda_i \phi_x \frac{\partial R_{i,x}}{\partial k_{i,x}} = 0.$$

Collecting marginal-revenue terms yields

$$[1 - \phi_x(r_x^{\text{adj}} + \lambda_i)] \frac{\partial R_{i,x}}{\partial k_{i,x}} = r_k,$$

and therefore

$$\text{MRPK}_{i,x} = \frac{r_k}{1 - \phi_x(r_x^{\text{adj}} + \lambda_i)} = r_k(1 + \tau_{i,x}).$$

The fixed financing cost $r_x^{\text{adj}} F_x$ affects participation but not the conditional capital choice. If the financing constraint is slack, then $\lambda_i = 0$ and

$$k_{i,x}^u = \left(\frac{(1 - r_x^{\text{adj}} \phi_x) \alpha \mathcal{Z}_{i,x}}{r_k} \right)^{1/(1-\alpha)}.$$

If it binds, then

$$\bar{k}_{i,x} = \left(\frac{\theta_x a_i - F_x}{\phi_x \mathcal{Z}_{i,x}} \right)^{1/\alpha}.$$

Strict concavity implies the active exporter chooses

$$k_{i,x}^* = \min\{k_{i,x}^u, \bar{k}_{i,x}\}.$$

Ordering under the benchmark. Under Assumption 1 both exporters are constrained, so $\bar{k}_{i,x} = ((\theta_x a_i - F_x)/(\phi_x \mathcal{Z}_x))^{1/\alpha}$ is increasing in a_i ; hence $a_1 < a_2$ implies $k_{1,x} < k_{2,x}$. Since $\text{MRPK}_{i,x} = \alpha \mathcal{Z}_x k_{i,x}^{\alpha-1}$ is decreasing in $k_{i,x}$ for $\alpha \in (0, 1)$, it follows that $\text{MRPK}_{1,x} > \text{MRPK}_{2,x}$.

E.3.2 Borrowing-cost versus pledgeability shocks

The model distinguishes a shock to the common working-capital borrowing cost, r_x^{adj} , from a shock to pledgeability, θ_x . For an unconstrained active exporter, $\lambda_i = 0$ and

$$k_{i,x}^u = \left(\frac{(1 - r_x^{\text{adj}} \phi_x) \alpha \mathcal{Z}_{i,x}}{r_k} \right)^{1/(1-\alpha)}.$$

Holding common price-index and rental-rate feedbacks fixed, a change in the common borrowing cost implies

$$d \log k_{i,x}^u = - \frac{\phi_x}{1 - \alpha} \frac{dr_x^{\text{adj}}}{1 - r_x^{\text{adj}} \phi_x},$$

which is common across firms within a narrow cell. By contrast, for a constrained exporter the binding pledgeability constraint gives

$$\bar{k}_{i,x} = \left(\frac{\theta_x a_i - F_x}{\phi_x \mathcal{Z}_{i,x}} \right)^{1/\alpha},$$

so

$$\frac{\partial \log \bar{k}_{i,x}}{\partial \log \theta_x} = \frac{1}{\alpha} \frac{\theta_x a_i}{\theta_x a_i - F_x} - \frac{1}{\alpha} \frac{\partial \log \mathcal{Z}_{i,x}}{\partial \log \theta_x}.$$

Within a narrow cell, the price-index feedback is common across Home exporters. Differencing across firms therefore leaves

$$\frac{\partial \log \bar{k}_{1,x}}{\partial \log \theta_x} - \frac{\partial \log \bar{k}_{2,x}}{\partial \log \theta_x} = \frac{1}{\alpha} \left[\frac{\theta_x a_1}{\theta_x a_1 - F_x} - \frac{\theta_x a_2}{\theta_x a_2 - F_x} \right] > 0$$

when $a_1 < a_2$ and both firms are active constrained exporters. Thus a common borrowing-cost shock moves interior exporters similarly within cells, whereas a pledgeability shock generates stronger proportional responses among the initially tighter, higher-MRPK constrained exporters.

E.3.3 Proof of Proposition 1

Proof. Consider a firm-specific local pledgeability perturbation evaluated at the common baseline $\theta_{i,x} = \theta_x$. For any constrained firm i ,

$$k_{i,x} = \left[\frac{\theta_{i,x} a_i - F_x}{\phi_x \mathcal{Z}_{i,x}} \right]^{1/\alpha}.$$

Log-differentiating with respect to $\log \theta_{i,x}$, holding common market shifters fixed, and evaluating at $\theta_{i,x} = \theta_x$ gives

$$\frac{\partial \log k_{i,x}}{\partial \log \theta_{i,x}} = \frac{1}{\alpha} \frac{\theta_x a_i}{\theta_x a_i - F_x}.$$

Differencing across firms gives

$$\frac{\partial \log k_{1,x}}{\partial \log \theta_{1,x}} - \frac{\partial \log k_{2,x}}{\partial \log \theta_{2,x}} = \frac{1}{\alpha} \left[\frac{\theta_x a_1}{\theta_x a_1 - F_x} - \frac{\theta_x a_2}{\theta_x a_2 - F_x} \right] > 0,$$

because the function $a \mapsto a/(a - c)$ has derivative $-c/(a - c)^2 < 0$ for $a > c > 0$, and the constrained-active assumption implies $\theta_x a_i > F_x$ for both firms. $\square$

E.3.4 Proof of Proposition 2

Proof. Because $\mathcal{Z}_{1,x} = \mathcal{Z}_{2,x}$, $k_{1,x} < k_{2,x}$ implies $\varpi_{1,x} > s_{1,x}$ because $\alpha \in (0, 1)$. Under the conditions of Proposition 2, Lemma 2 and Proposition 1 imply $d \log k_{1,x} - d \log k_{2,x} > 0$. Equation (E.11) then gives $d \log \Phi_x > 0$. $\square$

E.3.5 Proof of Proposition 3

Proof. For constrained exporters,

$$R_{i,x} = \frac{\theta_x a_i - F_x}{\phi_x}, \quad \frac{dR_{i,x}}{d\theta_x} = \frac{a_i}{\phi_x} > 0.$$

Since export-market expenditure D_x is fixed, Foreign residual revenue falls:

$$\mathcal{R}_{F,x} = D_x - \sum_{i=1}^2 R_{i,x}.$$

Because the Foreign price $\bar{p}_{F,x}$ is exogenous, CES demand implies

$$\mathcal{R}_{F,x} = D_x \left(\frac{P_x}{\bar{p}_{F,x}} \right)^{\sigma-1}.$$

Thus the fall in $\mathcal{R}_{F,x}$ implies $d \log P_x < 0$. For each constrained Home exporter,

$$d \log k_{i,x} = \frac{1}{\alpha} \frac{a_i d\theta_x}{\theta_x a_i - F_x} - d \log P_x > 0.$$

Therefore aggregate export capital rises.

Combining $d \log k_x > 0$ with Proposition 2 in (E.10) gives $E_x > 0$ and $d \log \mathcal{R}_x > 0$. Equation (E.10) also gives

$$d \log \mathcal{R}_x = (1 - w_x) E_x.$$

$\square$

E.3.6 Proof of Corollary 2

Proof. For a given $E_x > 0$, Proposition 3 gives

$$d \log \mathcal{R}_x = (1 - w_x) E_x.$$

Differentiating with respect to w_x yields

$$\frac{\partial}{\partial w_x} [(1 - w_x) E_x] = -E_x < 0.$$

The multiplier $1 - w_x$ comes from the CES price-index feedback in the export market: as Home export supply expands, the Home export-bundle price $P_{H,x}$ falls. With the Foreign import price $\bar{p}_{F,d}$ fixed, this decline is one for one the deterioration in Home's terms of trade, $d \log TOT_x = d \log P_{H,x} < 0$. The larger Home's initial export-market share w_x , the larger the price-index offset and the smaller the revenue gain from a given E_x . $\square$

E.3.7 Proof of Corollary 1

Proof. Under Assumption 1, firm 1's revenue share among Home exporters is

$$\varpi_{1,x} = \frac{\theta_x a_1 - F_x}{\theta_x(a_1 + a_2) - 2F_x}.$$

Differentiating gives

$$\frac{\partial \varpi_{1,x}}{\partial \theta_x} = \frac{F_x(a_2 - a_1)}{[\theta_x(a_1 + a_2) - 2F_x]^2} > 0.$$

At the same time, $\partial R_{2,x} / \partial \theta_x = a_2 / \phi_x > 0$. Firm 1 gains revenue share from firm 2, but firm 2 still expands in levels. $\square$

E.4 Welfare and Capital-Market Crowd-Out

This appendix derives the welfare expression and proves Proposition 4.

Under CES preferences, indirect utility equals real income $W = I/P_d$, where

$$I = \mathcal{R}_d + \mathcal{R}_x - T.$$

Capital and working-capital lenders are Home residents, so rental income $r_k K$ and working-capital interest $r_x^{adj}(\phi_x \mathcal{R}_x + 2F_x)$ are intra-Home transfers and net to zero in the aggregate income identity. Welfare therefore equals real Home gross output net of the fiscal cost of the intervention. Let

$$E_x \equiv \alpha d \log k_x + d \log \Phi_x, \quad E_d \equiv \alpha d \log k_d + d \log \Phi_d,$$

where $d \log \Phi_d = 0$ in the Home market because firms face no firm-specific Home-market wedge. Let $\chi_m \equiv \mathcal{R}_m / I$ and let w_d denote the Home-producer share of Home-market expenditure. Under the closure $D_d = I$, $\chi_d = w_d$ in equilibrium. The welfare change is

$$\hat{W} = \frac{\chi_x(1 - w_x)}{1 - \chi_d} E_x + \frac{\chi_d(1 - w_d)}{1 - \chi_d} E_d + \frac{w_d}{\sigma - 1} E_d - \frac{1}{1 - \chi_d} \frac{dT}{I}. \quad (\text{E.14})$$

The denominator $1 - \chi_d$ is the fixed-point multiplier generated by $D_d = I$.

E.4.1 Proof of Proposition 4

Proof. After imposing the CES price-index equations and the fixed point $D_d = I$, write capital demands as $\tilde{k}_d(r_k, \theta_x)$ and $\tilde{k}_x(r_k, \theta_x)$:

$$\tilde{k}_d(r_k, \theta_x) + \tilde{k}_x(r_k, \theta_x) = K_s(r_k).$$

For the capital-market comparative static, set $dT = 0$. Under the stability condition

$$K'_s(r_k) - \tilde{k}_{d,r} - \tilde{k}_{x,r} > 0,$$

the implicit-function theorem gives

$$\frac{dr_k}{d\theta_x} = \frac{\tilde{k}_{d,\theta} + \tilde{k}_{x,\theta}}{K'_s(r_k) - \tilde{k}_{d,r} - \tilde{k}_{x,r}} > 0. \quad (\text{E.15})$$

The export-demand shift gives $\tilde{k}_{x,\theta} > 0$. The Home-market demand feedback gives $\tilde{k}_{d,\theta} > 0$. Home-market capital changes according to

$$\frac{dk_d}{d\theta_x} = \tilde{k}_{d,\theta} + \tilde{k}_{d,r} \frac{dr_k}{d\theta_x}.$$

Thus Home-market crowd-out occurs if and only if

$$\frac{dk_d}{d\theta_x} < 0 \iff -\tilde{k}_{d,r} \frac{dr_k}{d\theta_x} > \tilde{k}_{d,\theta}.$$

The rental-rate response is decreasing in the capital-supply elasticity $K'_s(r_k)$; whenever the crowd-out condition holds, the absolute crowd-out effect is also decreasing in $K'_s(r_k)$. $\square$
